FINANCIAL
MATHEMATICS

BY

CLARENCE H. RICHARDSON, Ph.D.

Professor of Mathematics, Bucknell University

AND

ISAIAH LESLIE MILLER

*Late Professor of Mathematics, South Dakota State College
of Agriculture and Mechanic Arts*

PREFACE

This text is designed for a three-hour, one-year course for students who desire a knowledge of the mathematics of modern business and finance. While the vocational aspects of the subject should be especially attractive to students of commerce and business administration, yet an understanding of the topics that are considered—interest, discount, annuities, bond valuation, depreciation, insurance—may well be desirable information for the educated layman.

To live intelligently in this complex age requires more than a superficial knowledge of the topics to which we have just alluded, and it is palpably absurd to contend that the knowledge of interest, discount, bonds, and insurance that one acquires in school arithmetic is sufficient to understand modern finance. Try as one may, one cannot escape questions of finance. The real issue is: shall we deal with them with understanding and effectiveness or with superficiality and ineffectiveness?

While this text presupposes a knowledge of elementary algebra, we have listed for the student's convenience, page x, a page of important formulas from Miller and Richardson, *Algebra: Commercial—Statistical* that should be adequate for the well-prepared student. Although we make frequent reference to this Algebra in this text on Financial Mathematics, the necessary formulas are found in this reference list.

In the writing of this text the general student and not the pure mathematician has been kept constantly in mind. The text includes those techniques and artifices that many years of experience in teaching the subject have proved to be pedagogically fruitful. Some general features may be enumerated here: (1) The *illustrative examples* are numerous and are worked out in detail, many of them having been solved by more than one method in order that the student may compare the respective methods of attack. (2) *Line diagrams*, valuable in the analysis and presentation of problem material, have been given emphasis. (3) *Summaries* of important formulas occur at strategic points. (4) The *exercises* and *problems* are numerous, and they are purposely selected to show the applications of the theory to the many fields of activity. These exercises and problems are abundant, and no class will hope to do more than half of them. (5) Sets

iii

of *review problems* are found at the ends of the chapters and the end of the book.

A few special features have also been included: (1) *Interest* and *discount* have been treated with unusual care, the similarities and differences having been pointed out with detail. (2) The treatment of *annuities* is pedagogical and logical. This treatment has been made purposely flexible so that, if it is desired, the applications may be made to depend upon *two* general formulas. No new formulas are developed for the solution of problems involving annuities due and deferred annuities, and these special annuities are analyzed in terms of ordinary annuities. (3) The discussion of probability and its application to insurance is more extended than that found in many texts.

In this edition we are including Answers to the exercises and problems.

While we have exercised great care in the preparation of this book, it is too much to expect that it is entirely free from errors. For the notification of such errors, we shall be truly grateful.

USEFUL FORMULAS

From Miller and Richardson, *Algebra: Commercial—Statistical* *

CHAPTER I

1. Interest.—*Interest is the sum received for the use of capital.* Ordinarily, the interest and capital are expressed in terms of money. The capital is referred to as the *principal.* To determine the proper amount of interest to be received for the use of a certain principal, we must know the *time* that the principal has been in use and the *rate of interest* that is being charged. The rate of interest is the rate per *unit of time* that the *lender* receives from the *borrower* for the use of the money. The *rate of interest* may also be defined as the *interest earned* by *one unit of principal* in *one unit of time.* The unit of time is almost invariably one year, and the unit of principal one dollar. The sum of the principal and interest is defined as the *amount.*

When interest is paid only on the principal lent, it is called *simple interest.* In case the interest is periodically added to the principal, and the interest in the following period is each time computed on this principal thus formed by adding the interest of the previous period, then we speak of the interest as being *compounded*, and the sum by which the original principal is increased at the end of the time is called the *compound interest.* In this chapter only simple interest calculations will be considered.

2. Simple interest relations.—Simple interest on any principal is obtained by multiplying together the numbers which stand for the principal, the rate, and the time in years.

If we let $P =$ the principal,
$i =$ the rate of interest (in decimal form),
$n =$ the time (in years),
$I =$ the interest,
and $S =$ the amount,

it follows from the definitions of interest and amount that:

$$I = Pni, \tag{1}$$

and $$S = P + I. \tag{2}$$

1

From relations (1) and (2), we get

$$S = P + Pni = P(1 + ni),$$

or, $$P = \frac{S}{1 + ni}. \tag{3}$$

Relations (1) and (2) involve five letters (values). If we know any three of the values, the other two may be found by making use of these relations. Let us illustrate by examples.

Example 1. Find the interest on \$700 for 4 years at 5%. Find the amount.

Solution. Substituting in (1) the values, $P = 700$, $n = 4$, $i = 0.05$, we obtain

$$I = 700 \cdot 4 \cdot 0.05 = \$140.00, \text{ interest.}$$

And $$S = 700 + 140 = \$840.00, \text{ amount.}$$

Example 2. A certain principal in 5 years, at 5%, amounts to \$625. Find the principal.

Solution. $S = 625$, $n = 5$, $i = 0.05$.

Substituting in (3), we have

$$P = \frac{625}{1 + (5 \cdot 0.05)} = \frac{625}{1.25} = \$500, \text{ principal.}$$

Example 3. Find the rate if \$500 earns \$45 interest in 18 months.

Solution. Here, $P = 500$, $I = 45$, $n = 1\frac{1}{2}$.

From relation (1) we have,

$$i = \frac{I}{Pn} = \frac{45}{500 \cdot \frac{3}{2}} = 0.06 = 6\%.$$

Example 4. In what time will \$300 earn \$81 interest at 6%?

Solution. Here, $P = 300$, $i = 0.06$, $I = 81$.
From relation (1) we have,

$$n = \frac{I}{Pi} = \frac{81}{300(0.06)} = 4\frac{1}{2} \text{ years.}$$

Exercises

1. Making use of relations (1) and (2), express S in terms of I, n, and i.

2. Find the interest on $5,000 for $2\frac{1}{2}$ years at 5%. Find the amount.

3. Find the simple interest on $350 for 7 months at $6\frac{1}{2}\%$.

4. In what time will $750 earn $56.25 interest, if the rate is 5%?

5. At $4\frac{1}{2}\%$, what principal will amount to $925 in $3\frac{1}{2}$ years?

6. In what time will $2,500 amount to $2,981.25 at $3\frac{1}{2}\%$?

7. $2,400 amounts to $2,526 in 9 months. Find the rate.

8. What is the rate of interest when $2,500 earns $87.50 interest in 6 months?

9. What principal will earn $300 interest in 16 months, at 5%?

10. In what time will $305 amount to $344.65 at 4% interest?

11. What is the rate when $355 amounts to $396.42 in 2 years and 4 months?

12. What sum must be placed at interest at 4% to amount to $299.52 in 4 years and 3 months?

13. A building that cost $7,500, rents for $62.50 a month. If insurance and repairs amount to 1% each year, what is the net rate of interest earned on the investment?

14. If the interest on a certain sum for 4 months at 5% is $7.54, what is the sum?

15. What principal in 2 years and 5 months, will amount to $283.84, at $4\frac{1}{2}\%$?

16. At age 60 a person wishes to retire and invests his entire estate in bonds that pay 4% interest. This gives him a monthly income of $87.50. What is the size of his estate?

3. Ordinary and exact interest.—Most of the problems considered in simple interest involve intervals of time measured in days or parts of a year. The general practice is to calculate the interest for a fractional part of a year on the basis of 360 days in a year (12 months of 30 days each). When 360 days is used as the basis for our calculations, we have what is called *ordinary simple interest*. When the exact number of days between two dates is counted and 365 days to a year is used as the basis of our calculations, we have what is known as *exact simple interest*.

If we let $\quad d =$ the time in days,

$P =$ the principal,

$i =$ the rate,

$I_o =$ ordinary interest,

and $\quad I_e =$ exact interest, it follows that:

$$I_o = \frac{Pdi}{360}, \tag{4}$$

and

$$I_e = \frac{Pdi}{365}. \tag{5}$$

If we divide the members of (5) by the corresponding members of (4), we have

$$\frac{I_e}{I_o} = \frac{360}{365} = \frac{72}{73},$$

$$I_e = \frac{72}{73} I_o = I_o - \frac{1}{73} I_o. \tag{6}$$

We notice from (6) that the exact interest for any number of days is $72/73$ times the ordinary interest, or, in other words, exact interest is $I_o/73$ less than ordinary interest. Hence, *we may find the exact interest by first computing the ordinary interest and then diminishing it by $1/73$ of itself.*

Example. What is the ordinary interest on \$500 at 5% for 90 days? What is the exact interest?

Solution. Substituting in (4), we get

$$I_o = \frac{500 \cdot 90 \cdot 0.05}{360} = \$6.25.$$

$$6.25 \div 73 = 0.085+.$$

Hence, $I_e = 6.25 - 0.09 = \$6.16.$

Thus the ordinary interest is \$6.25 and the exact interest is **\$6.16**.

The exact interest could have been computed by applying (5), but the method used above is usually shorter, as will be seen after the reading of Art. 5.

4. Methods of counting time.—In finding the time between two dates the exact number of days may be counted in each month, or the time may be first found in months and days and then reduced to days, using 30 days to a month.

Example 1. Find the time from March 5 to July 8.

Solution. By the first method the time is 125 days. By the second method we get 4 months and 3 days or 123 days.

Either of these methods of computing time may be used where ordinary interest is desired, but when exact interest is required the exact time must be employed. Use of the following table will greatly facilitate finding the **exact** number of days between two dates.

TABLE SHOWING THE NUMBER OF EACH DAY OF THE YEAR COUNTING FROM
JANUARY 1

Day of month	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Day of month
1	1	32	60	91	121	152	182	213	244	274	305	335	1
2	2	33	61	92	122	153	183	214	245	275	306	336	2
3	3	34	62	93	123	154	184	215	246	276	307	337	3
4	4	35	63	94	124	155	185	216	247	277	308	338	4
5	5	36	64	95	125	156	186	217	248	278	309	339	5
6	6	37	65	96	126	157	187	218	249	279	310	340	6
7	7	38	66	97	127	158	188	219	250	280	311	341	7
8	8	39	67	98	128	159	189	220	251	281	312	342	8
9	9	40	68	99	129	160	190	221	252	282	313	343	9
10	10	41	69	100	130	161	191	222	253	283	314	344	10
11	11	42	70	101	131	162	192	223	254	284	315	345	11
12	12	43	71	102	132	163	193	224	255	285	316	346	12
13	13	44	72	103	133	164	194	225	256	286	317	347	13
14	14	45	73	104	134	165	195	226	257	287	318	348	14
15	15	46	74	105	135	166	196	227	258	288	319	349	15
16	16	47	75	106	136	167	197	228	259	289	320	350	16
17	17	48	76	107	137	168	198	229	260	290	321	351	17
18	18	49	77	108	138	169	199	230	261	291	322	352	18
19	19	50	78	109	139	170	200	231	262	292	323	353	19
20	20	51	79	110	140	171	201	232	263	293	324	354	20
21	21	52	80	111	141	172	202	233	264	294	325	355	21
22	22	53	81	112	142	173	203	234	265	295	326	356	22
23	23	54	82	113	143	174	204	235	266	296	327	357	23
24	24	55	83	114	144	175	205	236	267	297	328	358	24
25	25	56	84	115	145	176	206	237	268	298	329	359	25
26	26	57	85	116	146	177	207	238	269	299	330	360	26
27	27	58	86	117	147	178	208	239	270	300	331	361	27
28	28	59	87	118	148	179	209	240	271	301	332	362	28
29	29	..	88	119	149	180	210	241	272	302	333	363	29
30	30	..	89	120	150	181	211	242	273	303	334	364	30
31	31	..	90	...	151	...	212	243	...	304	...	365	31

NOTE.—For leap years the number of the day is one greater than the tabular number after February 28.

Example 2. Find the exact interest on $450 from March 20 to August 10 at 7%.

Solution. The exact time is 143 days.

Substituting in (5), we have

$$I_e = \frac{450 \cdot 143 \cdot 0.07}{365} = \$12.34.$$

Example 3. Find the ordinary interest in the above exercise.

Solution. Either 143 days (exact time) or 4 months and 20 days (140 days) may be used for the time when computing the ordinary interest. Using 143 days and substituting in (4), we have

$$I_o = \frac{450 \cdot 143 \cdot 0.07}{360} = \$12.51.$$

Using 140 days and substituting in (4), we have

$$I_o = \frac{450 \cdot 140 \cdot 0.07}{360} = \$12.25.$$

Either $12.51 or $12.25 is considered the correct ordinary simple interest on the above amount from March 20 to August 10. The computation of *ordinary interest* for the *exact time* is said to be done by the *Bankers' Rule.*

Exercises

1. Find the ordinary and exact interest on the following:
- a. $300 for 65 days at 6%.
- b. $475.50 for 49 days at 5%.
- c. $58.40 for 115 days at 7%.
- d. $952.20 for 38 days at 4½%.

2. Find the ordinary and exact interest on $2,400 at 8% from January 12 to April 6. Find the ordinary interest first and then use (6) to determine the exact interest.

3. Find the exact interest on $350 from April 10 to September 5 at 7%.

4. Find the ordinary interest on $850 from March 8 to October 5 at 6%.

5. How long will it take $750 to yield $6.78 exact interest at 6%?

6. How long will it take $350 to yield $3.65 ordinary interest at 5%?

7. The exact interest on $450 for 70 days is $7.77. What is the rate?

8. If the exact interest on a given principal is $14.40, find the ordinary interest for the same period of time by making use of (6).

9. The ordinary interest on a certain sum is $21.90. Find the exact interest for the same period of time.

10. What is the difference between the ordinary and exact interest on $2,560 at 6% from May 5 to November 3?

11. The difference between the ordinary and exact interest on a certain sum is $0.40. Find the exact interest on this sum.

5. The six per cent method of computing ordinary interest.— Ordinary simple interest may be easily computed by applying the methods of multiples and aliquot parts.

If we consider a year as composed of 12 months of 30 days each (360 days),

at 6%, the interest on $1 for 1 year is $0.06,
at 6%, the interest on $1 for 2 mo. (60 days) is $0.01,
at 6%, the interest on $1 for 6 days is $0.001.

That is, to find the interest on any sum of money at 6% for 6 days, point off three places in the principal sum; and for 60 days, point off two places in the principal sum.

By applying the above rule we may find the ordinary interest on any principal for any length of time at 6%. After the ordinary interest at 6% is found, it is easy to find it for any other rate. Also, by applying (6), Art. 3, the exact interest may be readily computed.

Example 1. What is the ordinary interest on $3,754 for 80 days at 6%?

Solution. $37.54 = interest for 60 days
 12.51 " " 20 " ($\frac{1}{3} \cdot$ 60 days)
 ─────
 $50.05 " " 80 days

Example 2. What is the ordinary simple interest on $475.25 for 115 days at 6%?

Solution. $4.753 = interest for 60 days
 2.376 = " " 30 " ($\frac{1}{2} \cdot$ 60 days)
 1.584 = " " 20 " ($\frac{1}{3} \cdot$ 60 days)
 0.396 = " " 5 " ($\frac{1}{4} \cdot$ 20 days)
 ─────
 $9.11 = interest for 115 days.

Example 3. Compute the ordinary interest on $865 for 98 days at 8%.

Solution.　$8.65　= interest for 60 days at 6%
　　　　　　4.325 =　　"　　"　30　"　"　"　(Why?)
　　　　　　0.865 =　　"　　"　6　"　"　"
　　　　　　0.288 =　　"　　"　2　"　"　"　(Why?)

　　　　　$14.128 = interest for 98 days at 6%
　　　　　　4.709 =　　"　　"　"　　"　　"　2% (⅓·6%)

　　　　　$18.84　= interest for 98 days at 8%.　(Why?)

Example 4. Find the simple interest on $580 for 78 days at 4½%.

Solution.　$5.80　= interest for 60 days at 6%
　　　　　　1.45　=　　"　　"　15　"　"　"
　　　　　　0.29　=　　"　　"　3　"　"　"

　　　　　$7.54　= interest for 78 days at 6%
　　　　　　1.885 =　　"　　"　"　　"　　"　1½% (Why?)

　　　　　$5.66　= interest for 78 days at 4½%.　(Why?)

Example 5. Find the exact simple interest on $2,500 for 95 days at 7%.

Solution.　$25.00 = interest for 60 days at 6%
　　　　　　12.50 =　　"　　"　30　"　"　"
　　　　　　2.08 =　　"　　"　5　"　"　"

　　　　　$39.58 = interest for 95 days at 6%
　　　　　　6.60 =　　"　　"　95　"　"　1%

　　　　　$46.18 = ordinary interest for 95 days at 7% (Why?)
　　　　　　0.63 = 46.18 ÷ 73

　　　　　$45.55 = exact interest for 95 days at 7%.　(Why?)

Exercises

1. Find the interest at 6% on:
　　$900 for 50 days, $365.50 for 99 days, $750 for 70 days, $870.20 for 126 days.

2. Solve 1, if the rate is 7½%.

3. Find the exact interest at 6% on:
　　$650 from March 3 to July 17
　　$800 from February 10, 1944, to May 5, 1944
　　$2,000 from August 10 to December 5.

4. Solve 3, if the rate is 8%.

5. A person borrowed $250 from a bank on July 5 and signed a **7%** note due November 20. On September 10 he paid the bank $100. What was the balance (including interest) due on the note November 20? (Use exact time.)

6. Solve 5, if 30 days is counted to each month.

7. Solve 5, if exact interest is used.

8. What is the difference between the exact and ordinary interest on $1,250 from March 10 to October 3 at 7%?

6. Present value and true discount.—In Art. 2 we found the relation between the principal, P, and the amount, S, to be expressed by the equations:

$$S = P(1 + ni) \quad \text{and} \quad P = \frac{S}{1 + ni}.$$

We may look upon P and S as equivalent values. That is, P, the value at the beginning of the period, is equivalent to S at the end of the period, and vice versa. The following line diagram emphasizes these ideas.
$$P = \frac{S}{1 + ni} \qquad\qquad S = P(1 + ni)$$

The quantity S is frequently called the *accumulated value* of P, and P is called the *present value* of S. Thus, the present value of a sum S due in n years is the principal P that will amount to S in n years. The quantity P is also called the discounted value of S due in n years. The difference between S and P, $S - P$, is called the *discount* on S as well as the interest on P. To distinguish it from Bank Discount (Art. 7) this discount on S at an interest rate $i\%$ is called the *true discount* on S. We thus have the several terms for P and S:

P	S
Principal	Amount
Present value of S	Accumulated value of P
Discounted value of S	Maturity value of P

$$S - P = \text{Interest on } P \text{ at interest rate } i$$

$$= \text{Discount on } S \text{ at interest rate } i$$

Example 1. Find the present value of a debt of $250 due in 6 months if the interest rate is 6%. Find the true discount.

Solution. Here, $S = 250$, $n = \frac{1}{2}$, and $i = 0.06$.
Substituting these values in formula (3), we get

$$P = \frac{250}{1 + \frac{1}{2}(0.06)} = \frac{250}{1.03} = \$242.72, \text{ present value.}$$

$$S - P = 250 - 242.72 = \$7.28, \text{ true discount.}$$

Example 2. A non-interest bearing note for $3,500, dated May 2 was due in 6 months. Assuming an interest rate of $7\frac{1}{2}\%$ find the value of the note as of July 5.

Solution.

> May 2 + 6 months = November 2, due date.
> From July 5 to November 2 = 120 days.
> The present value of the maturity value as of July 5 (or for 120 days) is required and $S = 3,500$, $n = \frac{1}{3}$, and $i = 0.075$.

Hence, $P = \dfrac{3,500}{1 + \frac{1}{3}(0.075)} = \dfrac{3,500}{1.025} = \$3,414.63.$

The following line diagram exhibits graphically the important relationships of the example.
Example 3. On May 2, A loaned B $3,500 for 6 months with interest at 6% and received from B a negotiable note. On July 5, A sold the note to C to whom money was worth $7\frac{1}{2}\%$. What did C pay A for the note?

Solution.

> Interest on $3,500 for 6 months at 6% = $105.00.
> $3,500 + $105.00 = $3,605, maturity value.
> May 2 + 6 months = November 2, maturity date.
> From July 5 to November 2 = 120 days.
> The present value of the maturity value as of July 5 (or for 120 days) is required and $S = 3,605$, $n = \frac{1}{3}$ and $i = 0.075$.

Hence, $$P = \frac{3{,}605}{1 + \frac{1}{3}(0.075)} = \frac{3{,}605}{1.025} = \$3{,}517.07,$$

the value of the note as of July 5.
The student will notice that in the solution of a problem of the above type we first find the maturity value of the note or debt and then find the present value of this maturity value as of the specified date.

Exercises

1. Accumulate (that is, find the accumulated value of) \$2,000 for 2 years at 5% simple interest.

2. Accumulate \$300 for 8 months at 6% simple interest.

3. At 6% simple interest find the present value of \$6,000 due at the end of 8 months. What is the discount?

4. Discount (that is, find the discounted value of) \$2,000 for 2 years at 5% simple interest.

5. Discount \$300 for 8 months at 6% simple interest.

6. Draw graphs of the following functions using n as the horizontal axis and S as the vertical axis:

    (a) $S = 100(1 + 0.06n) = 100 + 6n$.
    (b) $S = 100(1 + 0.04n) = 100 + 4n$.

7. Mr. Smith buys a bill of goods from a manufacturer who asks him to pay \$1,000 at the end of 60 days. If Mr. Smith wishes to pay immediately, what should the manufacturer be willing to accept if he is able to realize 6% on his investments?

8. Solve Exercise 7 under the assumption that the manufacturer can invest his money at 8%. Compare the results of Exercises 7 and 8 and note how the present value is affected by varying the interest rate.

9. I owe \$1,500 due at the end of two years and am offered the privilege of paying a smaller sum immediately. At which simple interest rate, 5% or 6%, would my creditor prefer to compute the present value of my obligation?

10.

    \$1,000.00   Lewisburg, Penna.
                                           June 1, 1944.

    Six months after date I promise to pay X, or order, one thousand dollars together with interest from date at 7%.

                               Signed, Y.

(a) What is the maturity value of the note?

(b) If X sold the note to W, to whom money was worth 6%, four months after date, what did W pay X for the note?

(c) What rate of interest did X earn on the loan?

11. Solve Exercise 10 under the assumption that money was worth 8% to W.

7. Bank discount.—*Bank discount is simple interest, calculated on the maturity value of a note from the date of discount to the maturity date, and is paid in advance.* If a bank lends an individual \$100 on a six months' note, and the rate of discount is 8%, the banker gives the individual \$96 now and collects \$100 when the note becomes due. If one wishes to discount a note at a bank, the bank deducts from the maturity value of the note the interest (bank discount) on the maturity value from the date of discount to the date of maturity. The amount that is left after deducting the bank discount is known as the *proceeds*. The time from the date of discount to the maturity date is commonly known as the *term of discount*. An additional charge is usually made by the bank when discounting paper drawn on some out-of-town bank. This charge is known as *exchange*. The bank discount plus the exchange charge gives the bank's *total charge*. The maturity value minus the total charge gives the proceeds (when an exchange charge is made).

The terms *face of a note* and maturity value of a note need to be explained. The maturity value may or may not be the same as the face value. If the note bears no interest they are the same, but if the note bears interest the maturity value equals the face value increased by the interest on the note for the term of the note.

The discount, maturity value, rate of discount, proceeds (when no exchange charge is made), and the term of discount are commonly represented by the letters D, S, d, P, and n, respectively. From the definitions of bank discount and proceeds we may write

$$D = Snd, \qquad (7)$$

and $$P = S - D = S - Snd = S(1 - nd). \qquad (8)$$

When applying formulas (7) and (8) we must express n in years and d in the decimal form.

The quantity P is frequently called the discounted value of S at the given rate of discount, and P is called the present value of S. S is also called the accumulated value of P. The difference between S and P, $S - P$, is called both the discount on S and the interest on P. In each instance

the calculation is at the discount rate d. The relations are pictured by the line diagram.

$$P \quad\quad n \text{ years at } d\% \quad\quad S$$

discount rate

$$P = S(1 - nd) \quad\quad\quad\quad S = \frac{P}{1 - nd}$$

$$S - P = \text{Interest on } P \text{ at discount rate } d$$

$$= \text{Discount on } S \text{ at discount rate } d$$

Example 1. A six months' note, without interest, for \$375, dated May 6, was discounted August 1, at 6%. Find the proceeds.

Solution.

> May 6 + 6 mo. = Nov. 6, due date.
> From August 1 to Nov. 6 = 97 days, term of discount.
> Discount on \$375 for 97 days = \$6.07, bank discount.
> \$375 − \$6.07 = \$368.93, proceeds.

Example 2. If the above note were a 5% interest-bearing note, what would be the proceeds?

Solution.

> May 6 + 6 mo. = Nov. 6, due date.
> From August 1 to Nov. 6 = 97 days, term of discount.
> Interest on \$375 for 6 mo. at 5% = \$9.38.
> \$375.00 + \$9.38 = \$384.38, maturity value.
> Discount on \$384.38 for 97 days at 6% = \$6.21, bank discount.
> \$384.38 − \$6.21 = \$378.17, proceeds.

\$375	\$378.17	\$384.38
May 6	Aug. 1	Nov. 6
	⊢——— 97 days ———⊣	
⊢——————————— 6 months ———————————⊣		
Example 3. Solve Example 2, if ¼% of the maturity value were charged for exchange.

Solution.

> May 6 + 6 mo. = Nov. 6, due date.
> From August 1 to Nov. 6 = 97 days, term of discount.
> Interest on \$375 for 6 mo. at 5% = \$9.38.

$375.00 + $9.38 = $384.38, maturity value.
Discount on $384.38 for 97 days at 6% = $6.21, bank discount.
¼% of $384.38 = $0.96, exchange charge.
$6.21 + $0.96 = $7.17, total charge made by the banker.
$384.38 − $7.17 = $377.21, proceeds.

Example 4.

$500.00   Lewisburg, Penna.
                                           February 1, 1944.

  Ninety days after date I promise to pay X, or order,
five hundred dollars together with interest from date at 6%.
                                           Signed, Y.

On March 10, X sold the note to banker B who discounted the note at
8%. What proceeds did X receive for the note?

Solution.

  90 days after Feb. 1, 1944 is May 1, 1944, the due date.
  From March 10 to May 1 is 52 days, the term of discount.
  The interest on $500 for 90 days at 6% = $7.50.
  $500.00 + $7.50 = $507.50, the maturity value.
  The discount on $507.50 for 52 days at 8% = $5.86, the bank
discount.
  $507.50 − $5.86 = $501.64, the proceeds.

```
$500                    $501.64                     $507.50
|-----------------------|---------------------------|
Feb. 1                 March 10                      May 1
|                       |<------- 52 days --------->|
|                       |                            |
|<------------------- 90 days ---------------------->|
```
In the solution of the above examples, certain fundamental facts have
been used, which we now point out.

If the note is given for a certain number of months, the maturity (due)
date is found by adding the number of months to the date of the note.
This is illustrated in Example 1. Thus, if a note for six months, is dated
May 6, it will be due on the corresponding (the 6th) day of the sixth month,
or November 6. November 30, would have been the due date of this note,
if it had been dated May 31. The correct date for three months after
November 30, 1930 is Feb. 28, 1931 and the correct date for three months
after November 30, 1931 is Feb. 29, 1932. What makes this difference?

If the term of the note is a fixed number of days, the due date is found by adding the number of days to the date of the note, using the exact number of days of the intervening months. Thus, 90 days after Feb. 1, 1932 is May 1, for the 28 days remaining in February + 31 days in March +30 days in April + 1 day in May = May 1. What is the correct date for 90 days after Feb. 1, 1931?

The term of discount is commonly found by counting the exact number of days between the date of discount and the due date. Thus, the term of discount in Example 1, is 97 days, being obtained as follows: 30 days remaining in August + 30 days in September + 31 days in October + 6 days in November = 97 days. The date of discount is excluded but the due date is included.

When February is an intervening month, use 28 days if no year date is given, but if it occurs in a leap year use 29 days.

These four examples illustrate all the fundamental facts that are used in discounting a note. They merit a careful study by the student.

Simple discount,* like simple interest, is seldom used in computations extending over a long period of time. In fact, the use of simple discount leads to absurd results in long-term transactions.

Illustration. At 6% discount, the present value of $1,000 due at the end of 20 years is, using $P = S(1 - nd)$,

$$P = \$1,000[1 - 20(0.06)] = -\$200.$$

8. Summary and extension.—We have used two methods to accumulate P and to discount S. The first method was based upon the simple interest rate i and the second was based upon the simple discount rate d. The relationships that we have developed are the following:

At simple interest.	At simple discount.
$I = Pni$	$D = Snd$
$S = P + I$	$S = P + D$
$S = P(1 + ni)$	$S = \dfrac{P}{1 - nd}$
$P = \dfrac{S}{1 + ni}$	$P = S(1 - nd)$

Banks and individuals frequently lend money at a discount rate instead of an interest rate. There are two reasons why the creditor may

---

* Bank discount is frequently referred to as *simple discount.*

prefer to lend at a discount rate.   First, the arithmetic is simplified when the maturity value is known, and second, a larger rate of return is obtained.

Thus, if I request a loan of $100 from a bank for six months at 6% *discount*, the banker actually gives me $97, collecting the *discount* of $3 *in advance*, and takes my non-interest-bearing note for $100.   Note the simplicity of the arithmetic: $P = 100(1 - 0.06/2) = 97.   Note also that the rate of return (the interest rate) is larger than 6%.   For we have $P = $97, n = \frac{1}{2}, S = $100, i = (\quad)$.   Using $S = P(1 + ni)$, we obtain

$$100 = 97\left(1 + \frac{i}{2}\right),$$

from which

$$i = 0.0619 \doteq 6.19\%.$$

However, the banker should not be accused of unfair dealing if he quotes me the 6% *discount rate* or if he states that he charges 6% *in advance*. He should be criticised if he quotes an interest rate and then charges a discount rate.   We shall return to the comparison of interest and discount rates in Art. 9.

Example 1.   I desire $900 as the proceeds of a 90 day loan from my banker B who charges 5% discount.   What sum will I pay at the end of 90 days?

Solution.   We have $P = $900, n = \frac{1}{4}, d = 0.05$.   From $P = S(1 - nd)$ we obtain

$$900 = S(1 - 0.05/4).$$

Solving, we find $S = $911.392.$

Exercises

Find the proceeds of the following notes and drafts:

	Face	Time	Date of Paper	Rate of Interest	Date of Discount	Rate of Discount	Rate of Collection
1.	$1,500	3 mo.	January 1		Jan. 25	6%	$\frac{1}{4}$%
2.	380	90 days	March 10	5%	Apr. 20	6%	
3.	2,000	6 mo.	August 1	6%	Nov. 10	7%	$\frac{1}{8}$%
4.	575	4 mo.	May 10		Aug. 1	7%	$\frac{1}{4}$%
5.	1,350	90 days	Feb. 1, 1928	6%	Mar. 7	8%	$\frac{1}{10}$%
6.	1,260	60 days	March 5	7%	April 1	6%	
7.	2,500	2 mo.	April 10		May 1	6%	$\frac{1}{10}$%

8. A \$2,500 6% interest-bearing note dated February 10, 1944 was due Sept. 1, 1944. It was discounted July 10 at $7\frac{1}{2}$%. What were the proceeds?

9. A person wishes to receive \$250 cash from a bank whose discount rate is 6%. He gives the bank a note due in 4 months. What should be the face value of the note?

10. Solve formula (8) for n and d.

11. The proceeds on a \$400 non-interest-bearing note discounted 78 days before maturity were \$394.80. What was the rate of discount?

12. A bank will loan a customer \$1,000 for 90 days, discounting the note at 6%. For what amount should the note be drawn?

13. How long before maturity was a \$450 note discounted, if the proceeds were \$444.14, the discount rate being 7%?

14. A 90-day 6% note of \$5,000, dated June 15, payable at a Louisville bank, was discounted at a Chicago bank July 20, at 7%. If the exchange charge was \$1.00, find the proceeds.

15. A six months' note bearing 5% interest was dated March 7, 1935. It was discounted at 6% on July 15, the bank charging \$18.45 discount. Find the face of the note.

16. A man received \$882 as the proceeds of a 90-day non-interest-bearing note. The face of the note was \$900. What was the rate of discount.

17. A bank's discount rate is 7%. What should be the face of the note if the proceeds of a 6 months' loan are to be \$2,000?

18. A 4 months' note bearing $4\frac{1}{2}$% interest, dated August 15, was discounted October 11, at 6%. The proceeds were \$791.33. Find the maturity value of the note. Find its face value.

19. A 90-day 7% note for \$1,200, dated April 1, was discounted June 10 at 6%. Find the proceeds.

20. How long before maturity was a \$500 6 months' 6% note discounted, if the proceeds were \$504.70, the discount rate being 8%?

21. The proceeds on a six months' 5% note, when discounted 87 days before maturity at 6% were \$1010.14. Find the face of the note.

22. Find the present value of \$1,000 due at the end of 20 years if 5% discount rate is used.

9. Comparison of simple interest and simple discount rates.—In Art. 8 we gave brief mention to the relation of interest rate to discount rate. This relation is so important that we will consider the problem more thoroughly at this point. We shall approach the question through a series of examples.

Example 1. If \$100, due at the end of one year, is discounted at 6%, what is the corresponding rate of interest?

Solution. We have $S = \$100$, $n = 1$, $d = 0.06$. In order to find i, we will first find P. Using $P = S(1 - nd)$, we have

$$P = 100(1 - 0.06) = \$94.$$

| $\$94$ | 1 year at $i\%$ | $\$100$ |

interest rate
Since $S - P$ is the interest on P, we may find i by using $I = Pni$. We have $I = \$6$, $n = 1$, $P = \$94$. Hence,

$$i = \tfrac{6}{94} = 0.06383 = 6.383\%$$

We might have employed the relation $S = P(1 + ni)$ to obtain the same result.

Example 2. If $\$100$, due at the end of 6 months, is discounted at 6%, what is the corresponding interest rate?

Solution. We have $S = \$100$, $n = \frac{1}{2}$, $d = 0.06$. From $P = S(1 - nd)$, we have

$$P = 100(1 - 0.06/2) = \$97.$$

| $\$97$ | 6 months at $i\%$ | $\$100$ |
interest rate

Since $S - P$ is the interest on P, we may find i by using $I = Pni$. We have $I = \$3$, $n = \frac{1}{2}$, $P = \$97$. Hence

$$97(i/2) = 3,$$

and
$$i = 0.0619 = 6.19\%.$$

Thus we notice that the interest rates corresponding to a given discount rate vary with the term; the longer the term, the larger the interest rate.

In general, we say that, for a given term, an interest rate i and a corresponding discount rate d are equivalent if the present values of S at i and d are equal. Thus, if P is the present value of S due in n years,

| P | n years | S |
we have

$$P = \frac{S}{1 + ni} \qquad \text{from (3),}$$

and
$$P = S(1 - nd)$$
from (8).

Hence,
$$\frac{S}{1 + ni} = S(1 - nd).$$

Solving we obtain

$$i = \frac{d}{1 - nd} \tag{9}$$

and
$$d = \frac{i}{1 + ni}. \tag{10}$$

From (9) we observe that for a given d the values of i increase as n increases. From (10) we observe that for a given i the values of d decrease as n increases.

The student will also observe from (10) that $i/(1 + ni)$ is the present value of i due in n years. That is, $i/(1 + ni)$ *in advance* is equivalent to i at the end of the term. But $i/(1 + ni)$ equals d. Hence d is equal to i paid *in advance*. Thus, we say *discount is interest paid in advance.*

Exercises

1. Solve Example 1 by using formula (3).

2. Solve Example 2 by using formula (3).

3. Employing equation (9) complete the table:

d	.08	.08	.08	.08
n	1	½	¼	⅛
i				

4. Employing equation (10) complete the table:

i	.08	.08	.08	.08
n	1	½	¼	⅛
d				

5. A obtains \$780 from Bank B. For this loan he gives his note for \$800 due in 60 days. At what rate does Bank B discount the note? What rate of interest does A pay?

6. A note for \$800, dated June 15, due in 90 days and bearing interest at 6%, was sold on July 1 to a friend to whom money was worth 5%. What did the friend pay for the note?

7. If the note described in Exercise 6 were sold to Bank B on July 5 at a discount rate of 7%, what would Bank B pay for the note?

8. $500.00   Pittsburgh, Penna.
                                                                        May 15, 1945.

Ninety days after date I promise to pay John Jones, or order, five hundred dollars together with interest at 6% from date.

Signed, Wm. Smith.

(a) Thirty days after date Jones sold the note to Bank B who discounted it at 7%. What did Jones receive for the note?
(b) Would it have been to Jones' advantage to have sold the note to friend C, to whom money was worth 7%, rather than to Bank B?

9.

$1,000.00   Chicago, Ill.
                                                                     May 15, 1945.

Six months after date I promise to pay Joe Brown, or order, one thousand dollars with interest from date at 5%.

Signed, Charles Paul.

(a) Two months after date Brown sold the note to Bank B who discounted it at 6%. What did Bank B pay for the note?
(b) Immediately after purchasing the note, Bank B sold the note to a Federal Reserve Bank at a re-discount rate of 4%. How much did Bank B gain on the transaction? [On transaction (b) use a 365-day year.]

10. Rates of interest corresponding to certain discount rates in the terms of settlement.—The subject of terms was discussed in *Alg.: Com.— Stat.*, p. 99.* An example will illustrate what is meant by the rates of interest corresponding to the rates of discounts of the terms of settlement.

Example 1. On an invoice of $1,000, a merchant is offered the following terms: 5, 3/30, n/90. What is the interest rate corresponding to each of the rates of discount?

Solution.

I. If the buyer pays the account immediately, he receives a discount of $50. That is, he settles the account for $950 which means that he receives $50 interest on $950 for 90 days. We may determine the interest rate by substituting in $I = Pni$, thus obtaining:

$$i = \frac{I}{Pn} = \frac{50}{950(\frac{1}{4})} = \frac{50}{237.50}$$
$$= 0.2105 = 21.05\%.$$

II. If the buyer settles the account at the end of 30 days, he receives a discount of $30. That is, the account is settled for $970 which

* Miller and Richardson, *Algebra: Commercial—Statistical*, D. Van Nostrand Co.

means $30 interest on $970 for 60 days. We determine the interest rate as in I and find,

$$i = \frac{30}{970(\frac{1}{6})} = \frac{180}{970}$$

$$= 0.1855 = 18.6\%$$

The buyer may have his business so well organized that he knows about what his money is worth to him in the running of the business. He can then determine the best offer, in the terms of sale, to accept. An example will illustrate.

Example 2. Assuming that money is worth 20% to the merchant in his business, which is the best offer in Example 1?

Solution. To answer this question we must compare the present values of the separate offers. That is, which offer has the least present value assuming money worth 20%?

I. 5% discount on $1,000 means a discount of $50. Hence the present value of this offer is $1,000 − $50 = $950.

II. 3% discount on $1,000 means a discount of $30 at the end of 30 days. Hence, $970 is required to settle the account at the end of 30 days. Now, the present value of $970 is

$$P = \frac{970}{1 + \frac{1}{12}(0.20)} = \frac{970}{1.0167} = \$954.06.$$

III. Here the present value of $1,000 for 90 days at 20% is required. Hence,

$$P = \frac{1,000}{1 + \frac{1}{4}(0.20)} = \frac{1,000}{1.05}$$

$$= \$952.38.$$

We notice that the 5% cash discount is the best offer (assuming money worth 20%) since it gives the least present value for the invoice.

Exercises

1. Determine the interest rates corresponding to bank discount rates of (a) 7% 90 days before maturity; (b) 7½% 60 days before maturity; (c) 6% 6 months before maturity; (d) 8% 4 months before maturity.

2. In discounting a 4 months' note a bank earns 9% interest. What rate of discount does it use?

3. What are the rates of discount corresponding to (a) 7% interest earned on a note discounted 90 days before maturity; (b) 8% interest earned on a note discounted 4 months before maturity; (c) 6% interest earned on a note discounted 6 months before maturity?

4. What rate of interest is earned on money used in discounting bills at a discount rate of 9% per annum?

5. What is the rate of discount at which a bank may as well employ its funds as to lend money at an interest rate of 8%?

6. A merchant has the privilege of 90 days credit or 3% off for cash. What rate of interest does he earn on his money if he pays cash?

7. A merchant bought a bill of goods amounting to $2,500 and received the following terms: 4, 3/10, $n/90$. What is the interest rate corresponding to each of the rates of discount?

8. Assuming that money is worth 15% to the merchant in the conducting of his business, which is the best offer in Exercise 7? (See illustrative Example 2, Art. 10.)

9. On an invoice of $4,200, a merchant is offered 60 days credit or a discount of 3% for cash. Not having the money to pay cash, he accepts the credit terms. What rate of interest does he pay on the net amount of the bill? How much would he have saved if he had borrowed the money at 7% and paid cash?

10. 7% interest was earned in discounting a note 90 days before maturity; 6% was earned in discounting a 4 months' note; and 5% was earned in discounting a 9 months' note. What were the corresponding discount rates?

11. Assuming money worth 20% in one's business, which one of following offers is the most advantageous to the buyer: 6, 5/30, $n/4$ mos.? (Assume an invoice of $100.)

12. Solve Exercise 11, assuming money worth 18%.

13. A bank used a discount rate of 6% in discounting a 4 months' note. What rate of interest was earned on the transaction?

14. Assuming money worth 12%, which one of the following offers is the most advantageous to the buyer: 6, 4/30, $n/4$ mos.?

11. Exchanging debts.—When two or more debts (obligations) are to be compared we must know when each debt is due and then compare their values at some specified time. The value of a debt at a specified time depends upon the rate of interest that is used. Let us suppose that a debt of $200 is due in 2 months and one of $205 is due in 8 months. Assuming money worth 6%, compare their values now. The value of the first debt at this time is

$$\frac{200}{1 + \frac{1}{6}(0.06)} = \frac{200}{1.01} = \$198.02 \quad [(3), \text{ Art. 2}]$$

and the value of the second debt at this time is

$$\frac{205}{1 + \frac{2}{3}(0.06)} = \frac{205}{1.04} = \$197.12.$$

Six months from now the first debt would be 4 months past due and should draw interest for that time. The second debt would not be due for 2 months and should be discounted for that time. Then their values 6 months from now would be

$$200[1 + \tfrac{1}{3}(0.06)] = 200(1.02) = \$204.00$$

and
$$\frac{205}{1 + \tfrac{1}{6}(0.06)} = \frac{205}{1.01} = \$202.97.$$

We notice that the first debt has a greater value on both dates of comparison. If 6% is used the value of the first debt will always be greater than that of the second.

If 4% were used their values on the above dates would be \$198.67, \$199.67 and \$202.67, \$203.64; respectively. That is, if 4% interest is assumed the second debt has a greater value at all times.

If 6% interest is assumed, the sum of the values of the above debts at the present is \$395.14. This is shown by the equation

$$\frac{200}{1.01} + \frac{205}{1.04} = 395.14.$$
We say that the sum of the values of \$200 due in 2 months and \$205 due in 8 months is equal to \$395.14 due now, if money is assumed to be worth 6%. Also, the sum of the values of \$200 due in 2 months and \$205 due in 8 months is equal to the sum of the values of \$201.97 due in 3 months and \$201.97 due in 6 months, if 6% interest is assumed. This may be shown by comparing the two sets of debts on some common date. Suppose we take 8 months from now as a common date. Then

$$200(1.03) + 205 = 411.00$$

and
$$201.97(1.025) + 201.97(1.01) = 411.01.$$

Whenever the value of one set of obligations is equal to the value of another set of obligations on a common date, the one set may be exchanged for the other set, and the values of the two sets are said to be *equivalent*. The common date used for the date of comparison is usually known as the *focal date*, and the equality which exists, *on the focal date*, between the values

of the two sets of obligations is called an *equation of value.* An example will illustrate the meaning of focal date and equation of value.

Example 1. A person owes $600 due in 4 months and $700 due in 9 months. Find the equal payments necessary to equitably discharge the two debts, if made at the ends of 3 months and 6 months, respectively, assuming 6% simple interest.

Solution. We choose the end of 9 months for our focal date and set up the equation of value.*
Let $x =$ the number of dollars in each of the equal payments.

The time from the date of making the first payment x until the focal date is 6 months and the payment will accumulate to

$$[1 + \tfrac{1}{2}(0.06)]x = (1.03)x \text{ on the focal date.}$$

The second payment is made 3 months before the focal date and it will accumulate to

$$[1 + \tfrac{1}{4}(0.06)]x = (1.015)x \text{ on the focal date.}$$

The $600 debt is due in 4 months, just 5 months before the focal date, and will accumulate to

$$600[1 + \tfrac{5}{12}(0.06)] = 615.00 \text{ on the focal date.}$$

The $700 debt is due on the focal date and will be worth $700 on that date.

The equation of value becomes

$$(1.03)x + (1.015)x = 615 + 700,$$

$$(2.045)x = 1,315,$$

$$x = \$643.03, \text{ the amount of each of the equal payments.}$$

In setting up an equation of value, we assume that the equation is true for any focal date. That is, we assume that if the value of one set of debts is equal to the value of another set of debts on a given focal date, then the values are equal on any other focal date. If in the above prob-

---

*In the construction of the line diagram, (a) place at the respective points the *maturity* values, and (b) place the payments and the debts at different levels.

lem we had taken 3 months from now for the focal date, we would have obtained $643.07 for the amount of one of the equal payments. Using 5 months from now as focal date we obtain $643.02 as one of the equal payments. We notice that a change in the focal date changes the values of the payments, but this change is very slight and for short periods of time we may neglect the small differences caused by different choices of focal dates and choose the one that is most convenient. (In Art. 19 it will be shown that the amount x is independent of the focal date when the computations are based upon compound interest.) The last date occurring seems to be the most convenient, for then no discount is involved.

Example 2. Solve Example 1, assuming that the original debts bear 7% interest to maturity. Choose 9 months from now as the focal date.

Solution. $600 at 7% amounts to $614 in 4 months and on the focal date its amount is

$$614[1 + \tfrac{5}{12}(0.06)] = 614(1.025) = \$629.35.$$

$700 at 7% amounts to $736.75 in 9 months and on the focal date its amount is this maturity value ($736.75).
The equation of value becomes

$$(1.03)x + (1.015)x = 629.35 + 736.75,$$

$$(2.045)x = 1,366.10,$$

$$x = \$668.02, \text{ the amount of one of the equal payments.}$$

12. To find the date when the various sums (debts) due at different times may be paid in one sum.—A may owe B several sums (debts) due at different times and may desire to cancel all of them at one time by paying a single amount equal to the sum of the **maturity values** of the several debts. The problem, then, is to find a date when the single amount may be paid without loss to either A (debtor) or B (creditor). Evidently, this should be at a time when the total interest gained by the debtor on the sums past due would balance the total interest lost on the sums paid before they are due. The date to be found is known as the *equated date*.

The solutions of problems of this character may be effected by either

of two methods. We may base our procedure upon a *simple interest rate i* and choose the *latest date* mentioned in the problem as the focal date, or we may base our procedure upon a *simple discount rate d* and choose the *earliest date* mentioned in the problem as the focal date. If the former method is followed all sums will accumulate at i to the focal date whereas if the latter method is adopted all sums will be discounted at d to the focal date.

Example. A owes B the following debts: $200 due in 60 days, $400 due in 90 days, and $600 due in 120 days. Find the time when these debts may be canceled by a single payment of their sum, $1,200.

Solution. We have the debts and the payment as shown by the line diagram.
Let n days from now be the equated date.

We choose the focal date at the latest date, 120 days from now, and assume an interest rate i.

The first debt, $200, will be at interest for 60 days and its value on the focal date is

$$200\left(1 + \frac{60}{360}i\right).$$

The second debt, $400, will be at interest for 30 days and its value on the focal date is

$$400\left(1 + \frac{30}{360}i\right).$$

The third debt, $600, due on the focal date, bears no interest and hence its value then is

$$600\left(1 + \frac{0}{360}i\right).$$

The single payment, $1,200, will be at interest $(120 - n)$ days and thus its value on the focal date is

$$1{,}200\left(1 + \frac{120 - n}{360}i\right).$$

Expressing by an equation the fact that the value of the payment on the focal date is equal to the sum of the maturity values of the debts on that date, we have

$$1{,}200\left(1 + \frac{120 - n}{360}\,i\right)$$

$$= 200\left(1 + \frac{60}{360}\,i\right) + 400\left(1 + \frac{30}{360}\,i\right) + 600\left(1 + \frac{0}{360}\,i\right)$$

which reduces to

$$1{,}200\left(\frac{120 - n}{360}\,i\right) = 200\left(\frac{60}{360}\,i\right) + 400\left(\frac{30}{360}\,i\right) + 600\left(\frac{0}{360}\,i\right).$$

Note. The student should note that the last equation written above simply states that the interest on the payment equals the sum of the interest increments on the debts, all calculated from their due dates to the focal date.

Multiplying the last equation by 360 and dividing through by $100i$, we get

$$12(120 - n) = 2(60) + 4(30)$$

$$1{,}440 - 12n = 120 + 120$$

$$-12n = -1{,}200$$

$$n = 100.$$

Hence, the \$1,200 may be paid 100 days from now and the equities be the same as if the debts were paid as originally scheduled.

Note. The fact that the interest rate i divides out as a factor in solving the equation of value shows that the value of n is independent of i.

Exercise. Solve the preceding example by assuming a discount rate d and choosing (a) the earliest date, 60 days, as the focal date, and (b) the present or "now" as the focal date.

By following a line of reasoning similar to that used in solving the preceding example, we will solve the general problem.

Problem. Let $D_1, D_2, \cdots, D_k$ be k debts due in $n_1, n_2, \cdots, n_k$ years respectively, and let their maturity values be $S_1, S_2, \cdots, S_k$. We wish to find *the equated time*, that is, the time when the k debts may be settled by a single payment of $S_1 + S_2 + \cdots + S_k$.

Solution. We shall assume $n_1 < n_2 < n_3 < \cdots < n_k$, and we shall take the latest date, n_k, to be the focal date. Also we let n years from now be the equated time. The diagram gives us the picture.
Assuming an interest rate i, the accumulated values of S_1, S_2, etc., at n_k are $S_1[1 + (n_k - n_1)i]$, $S_2[1 + (n_k - n_2)i]$, etc., we then have the equation of value

$$[S_1 + S_2 + \cdots + S_k][1 + (n_k - n)i] =$$
$$S_1[1 + (n_k - n_1)i] + S_2[1 + (n_k - n_2)i] + \cdots + S_k[1 + (n_k - n_k)i].$$

Subtracting $S_1 + S_2 + \cdots + S_k$ from both sides of the equation we have

$$(S_1 + S_2 + \cdots + S_k)(n_k - n)i =$$
$$S_1(n_k - n_1)i + S_2(n_k - n_2)i + \cdots + S_k(n_k - n_k)i.$$

Note. This equation shows that the interest on the payment equals the sum of the interest increments on the maturity values, all calculated from their due dates to the focal date.

Solving for n we obtain

$$n = \frac{S_1 n_1 + S_2 n_2 + S_3 n_3 + \cdots + S_k n_k}{S_1 + S_2 + S_3 + \cdots + S_k}. \tag{12}$$

If D_1, D_2, $\cdots$, D_k are not interest-bearing debts, $D_1 = S_1$, $D_2 = S_2$, $\cdots$, $D_k = S_k$, and equation (12) becomes

$$n = \frac{D_1 n_1 + D_2 n_2 + \cdots + D_k n_k}{D_1 + D_2 + \cdots + D_k}. \tag{12'}$$

If the debts involve short periods of time it is usually more convenient to express n, n_1, n_2, etc., in terms of either months or days.

Exercise. Derive formula (12) by assuming a discount rate d and choosing "now" as the focal date.

Exercise. The equated time has an interesting "teeterboard" property in that it is the "center of balance" when the maturity values are suspended as weights with lever arms measured from n. That is, let the lever arms be $\bar{n}_1 = n_1 - n$, $\bar{n}_2 = n_2 - n$, etc., respectively. Then,

$$S_1 \bar{n}_1 + S_2 \bar{n}_2 + S_3 \bar{n}_3 + \cdots + S_k \bar{n}_k = 0.$$

13. To find the equated date of an account.—To find the equated date of an account means we must find *the date when the balance of the account can be paid without loss to either the debtor or the creditor.*

As in Art. 12, we assume that the sum of the values, as of the focal date, of all credits including the balance, is equal to the sum of the values on that date of all debits. Obviously, we may select the focal date in many ways. We may, for example, choose the earliest date mentioned in the problem as the focal date and *discount* all credits and debts to this

point. We shall illustrate this procedure in our discussion first by a specific example and then by the general problem.

Example. What is the equated date of the account?

1944	1944
May 1, Mdse., $1,500	May 11, Cash, $400
June 19, Mdse., $1,000	May 31, Cash, $900

Solution. The total of the debts is $2,500 and the total of the credits is $1,300. Our problem is to find the date when the balance, $1,200, can be paid without loss to either the debtor or the creditor. The line diagram gives us the picture.

We let the earliest date, May 1, be the focal date. Let n days from May 1 be the equated date. We assume a discount rate d and set up the equation of value.

$$400\left(1 - \frac{10}{360}d\right) + 1{,}200\left(1 - \frac{n}{360}d\right) + 900\left(1 - \frac{30}{360}d\right)$$
$$= 1{,}500\left(1 - \frac{0}{360}d\right) + 1{,}000\left(1 - \frac{49}{360}d\right).$$

Subtracting 2,500 from both sides of the equation and multiplying by (-1), we get

$$400\left(\frac{10}{360}d\right) + 1{,}200\left(\frac{n}{360}d\right) + 900\left(\frac{30}{360}d\right)$$
$$= 1{,}500\left(\frac{0}{360}d\right) + 1{,}000\left(\frac{49}{360}d\right).$$

Note. This equation shows that the sum of the discounted values of the credits, as of May 1, equals the sum of the discounted values of the debts as of the same date. Further, since the last equation written above is divisible by d, the value of n is independent of the discount rate.

Multiplying the last equation by 360 and dividing by $100d$, we have

$$40 + 12n + 270 = 490$$
$$12n = 180$$
$$n = 15 \text{ days.}$$

Thus the equated date is 15 days after May 1, or May 16.

Exercise. Solve the preceding example by assuming an interest rate i and choosing the latest date, June 19, as the focal date.

By following a line of reasoning similar to that used in solving the preceding example, we will solve the general problem.

Problem. Let D_1, D_2, D_3, $\cdots$, D_k be k debts due in n_1, n_2, n_3, $\cdots$, n_k years from now respectively, and let their maturity values be S_1, S_2, S_3, $\cdots$, S_k. Also, let C_1, C_2, C_3, $\cdots$, C_m be m credits entered o_1, o_2, o_3, $\cdots$, o_m years from now respectively. We wish to find the equated date of the account, that is, the date when the balance B,

$$B = (S_1 + S_2 + S_3 + \cdots + S_k) - (C_1 + C_2 + C_3 + \cdots + C_m),$$

can be paid without loss to either debtor or creditor.

Solution. We shall assume $n_1 < n_2 < n_3 < \cdots < n_k$ and $o_1 < o_2 < o_3 < \cdots < o_m$. For the sake of variety we shall take "now" to be the focal date. We assume a discount rate d and let n equal the number of years from now to the equated date. The line diagram gives us the picture.
By equating the sum of the credits, including the balance, discounted to the present, O, and the sum of the debts as of the same date, we have the equation of value

$$C_1(1-o_1d)+C_2(1-o_2d)+C_3(1-o_3d)+\cdots+C_m(1-o_md)+B(1-nd)$$
$$=S_1(1-n_1d)+S_2(1-n_2d)+S_3(1-n_3d)+\cdots+S_k(1-n_kd).$$

Subtracting $C_1 + C_2 + C_3 + \cdots + C_m + B$ from both sides of this equation, then multiplying by (-1), we get

$$C_1o_1d + C_2o_2d + C_3o_3d + \cdots + C_mo_md + Bnd$$
$$= S_1n_1d + S_2n_2d + S_3n_3d + \cdots + S_kn_kd.$$

Note. This last equation shows that the sum of the discounted values of the payments equals the sum of the discounted values of the debts, all discounted to the focal date, "now." Also, since every term of this equation contains the factor d, which may be divided out, the equated date is independent of d.

Dividing out d and solving for n, we get, replacing B by its value,

$$n = \frac{(S_1n_1+S_2n_2+S_3n_3+\cdots+S_kn_k)-(C_1o_1+C_2o_2+C_3o_3+\cdots+C_mo_m)}{(S_1+S_2+S_3+\cdots+S_k)-(C_1+C_2+C_3+\cdots+C_m)}.$$

$$(13)$$

If the debts are not interest-bearing, $S_1 = D_1$, $S_2 = D_2$, etc., in which case (13) becomes

$$n = \frac{(D_1n_1+D_2n_2+D_3n_3+\cdots+D_kn_k)-(C_1o_1+C_2o_2+C_3o_3+\cdots+C_mo_m)}{(D_1+D_2+D_3+\cdots+D_k)-(C_1+C_2+C_3+\cdots+C_m)}. \tag{13'}$$

In practice we usually let the earliest date mentioned in the problem be "now," then $n_1 = O$ and the first term in the numerator vanishes.

When accounts involve short periods of time, we usually express n, n_1, n_2, n_3, $\cdots$, n_k, o_1, o_2, o_3, $\cdots$, o_m, in months or days.

Note. *An account becomes interest-bearing on the equated date and the debtor should pay interest on the balance of the account from the equated date until the balance is paid.*

Exercise. Derive formula (13) by assuming an interest rate i and choosing the latest date, n_k, as the focal date.

Exercises

1. An obligation of \$500 is due in 3 months and another obligation of \$520 is due in 9 months. Assuming money worth 6% simple interest, compare the values of these obligations (a) now, (b) 6 months from now, (c) 12 months from now.

2. Solve Exercise 1, assuming money worth 9% simple interest.

3. A note for \$600 drawing 5% simple interest will be due in 5 months, and another note for \$600 drawing 6% interest will be due in 9 months. Assuming money worth 7% simple interest, compare the values of these obligations 7 months from now.

4. Solve Exercise 3, assuming money worth 8% simple interest.

5. A owes B \$500 due in 3 months, \$600 due in 5 months, and \$700 due in 8 months. Find the equal payments to be made at the end of 6 months and 12 months, respectively, which will equitably discharge the three debts if money is worth 5%.

6. Assuming 6% simple interest, find the equal payments that could be made in 3 months, 6 months, and 9 months, respectively to equitably discharge obligations of \$500 due in 2 months and \$800 due in 5 months.

7. Solve Exercise 5, assuming that the three debts draw 6% simple interest.

8. A owes B the following debts: \$700 due in 5 months at 7% interest, \$500 due in 6 months at 7% interest, and \$600 due in 9 months at 5% interest. Assuming money worth 6%, find the single payment that is necessary to equitably discharge the above debts 8 months from now.

9. Find the time when the following items may be paid in a single sum of \$3,000: \$1,500 due May 1, \$500 due June 12, \$800 due June 25, and \$200 due July 20.

10. Find the time when the following items may be paid in a single sum of \$2,300: \$500 due March 1, \$300 due April 10, \$800 due April 25, and \$700 due June 1.

11. Find the time when obligations of \$350 due in 2 months, \$600 due in 3 months, and \$850 due in 6 months may be settled by a single payment of \$1,800.

12. Find the time for settling in one payment of \$1,600 the following debts: \$200 due in 3 months, \$400 due in 5 months, \$300 due in 6 months, and \$700 due in 8 months.

13. Find the date when the following items may be paid in a single sum of $2,000:

Sept. 1, Mdse., 30 days, $400*
Sept. 27, Mdse., 60 days, $500
Nov. 9, Mdse., 2 months, $1,100

Check the correctness of the date by assuming 6% simple interest and showing that the interest on the past due items as of the equated date is the same as the interest from the equated date to the due dates of the items not yet due.

Find the time when the following accounts may be paid in single amounts:

14.   1941
January 2, Mdse., 30 da., $800
January 17, Mdse., 1 mo., $500
March 1, Mdse., 2 mo., $300
March 30, Mdse., net $400

15.   1941
July 1, Mdse., 60 da., $550
July 10, Mdse., 1 mo., $450
August 1, Mdse., 2 mo., $750
Sept. 1, Mdse., net, $350
Sept. 10, Mdse., 30 da., $400

Find the time when the balance of the following accounts may be paid in single amounts:

16.   1941
April 1, Mdse., $700
April 10, Mdse., $500
July 1, Mdse., $800

1941
April 20, Cash, $400
May 10, Cash, $300
May 31, Cash, $300

17.   1941
July 1, Mdse., net, $575
July 5, Mdse., 1 mo., $435
Aug. 1, Mdse., 60 da., $990

1941
July 10, Cash, $440
Aug. 1., Cash, $720

18.   1944
January 1, Balance, $1,900
January 20, Mdse., 1 mo., $1,450
March 10, Mdse., Net, $1,325

1944
Jan. 15, Cash, $1,560
Jan. 30, Note, † 2 mo., $1,200
Feb. 1, Note, † 90 da., with interest, $500

19.   1944
May 1, Balance, $500
May 10, Mdse., 2 mo., $1,000
June 7, Mdse., 30 days, $2,000
July 1, Mdse., $600

1944
May 15, Cash, $700
June 20, Cash, $1,000
July 10, Cash, $400

* When terms of credit are given on the different items, we must first find the due date of each item.

† When a note is given without interest, the time is figured to the due date of the note, but when the note bears interest the time is figured to the date that the note is given.

<div align="center">Review Problems *</div>

1. A man derives an income of $205 a year from some money invested at 4% and some at 5%. If the amounts of the respective investments were interchanged, he would receive $200. How much has he in each investment?

2. A man has one sum invested at 4% and another invested at $5\frac{1}{2}\%$. His total annual interest is $320. If both sums had been invested at 6%, the annual interest would have been $390. Find the sums invested at each rate.

3. A man made three loans totaling $15,000, the first at 4%, the second at 5% and the third at 6%, receiving for the whole $770 per year. The interest on the second part is $70 less than on the sum of the first and third parts. How was the money divided?

4. A man has three sums invested at 4%, 6%, and 7% respectively, the total interest received being $280. If the three sums had been invested at 6%, 7% and 4% respectively, the total interest would have been $305. How much was invested at each rate, if the sum invested at 4% was $500 more than the sum invested at 7%?

5. One half of a man's property is invested at 4%, one third at 5%, and the rest at 6%. How much property has he if his income is $560?

6. One man can do a piece of work in 10 days, another in 12 days, and a third in 15 days. How many days will it require all of them to do it when working together?

7. A certain tank can be filled by a supply pipe in 6 hours. It can be filled by another pipe in 8 hours and a third pipe can empty it in 12 hours. If all three pipes are running at the same time, how soon will it be filled?

8. How much cream that contains 32% butter fat should be added to 500 pounds of milk that contains 3% butter fat to produce a milk with 4% butter fat?

9. A merchant desires to mix coffee selling at 24 cents a pound with 80 pounds selling at 30 cents a pound and 60 pounds selling at 33 cents a pound to produce a mixture which he can sell at 28 cents a pound. How many pounds of the 24 cent coffee must he use?

10. How large a 6% interest-bearing note should be given April 1 to cancel a debt of $1,200 due July 1?

11. What is the difference between the true and bank discount on a debt of $1,000 due in 4 months, the interest rate and the discount rate being $7\frac{1}{2}\%$?

12. A note for $2,500, bearing 5% interest, dated June 1 was due November 10. What should be paid for this note August 18, (a) if 6% simple interest is to be realized? (b) if 6% discount is to be realized?

13. A note of $500, bearing 6% interest, is dated March 1. If it is due in 4 months, what would be its value May 1 at $4\frac{1}{2}\%$?

14. A merchant is offered a bill of goods invoiced at $748.25 on 4 months' credit. As a settlement he gives his note with interest at $7\frac{1}{2}\%$ for a sum which, at maturity, will cancel the debt. Find the face of the note.

15. On March 5, a bill of merchandise valued at $3,000 was bought on 6 months' credit. On May 8, $1,500 was paid on the account. On July 22 the present value of the balance of the debt was paid. Assuming money worth 6%, find the amount of the final payment.

* Many of these problems are review problems of algebra. For additional review problems in interest and discount, see end of this book.

16. A piece of property was offered for sale for $2,900 cash or for $3,000 due in 6 months without interest. If the cash offer was accepted, what rate of interest was realized?

17. The cash price of a certain article is $90 and the price on 6 months' credit is $95. How much better is the cash price for the purchaser, if money is worth 7%?

18. The present value at 5% of a debt due in 72 days is $396.04. What is the amount of the debt?

19. Find the true discount on a debt of $3,600 when paid 6 months before maturity, assuming 5% simple interest.

20. A father wishes to provide an educational fund of $2,000 for his daughter when she reaches the age of 18. What sum should he invest at 4% simple interest on her thirteenth birthday in order that his wishes may be realized?

21. What cash payment on July 1 will cancel a debt of $2,400 due December 8, if money is worth 8%?

22. A merchant buys a bill of goods from a jobber for $1,500 on 4 months' credit. If the jobber can realize 6% simple interest on his money, what cash payment should he be willing to accept from the merchant?

23. A man borrows $10,000. He agrees to pay $1,000 at the end of each year for 10 years and 4% simple interest on all unpaid amounts. Find the total sum paid in discharging the debt.

24. Find the sum: $1 + (1.06) + (1.06)^2 + \cdots + (1.06)^9$.

25. Find the sum: $(1.03)^{-10} + (1.03)^{-9} + (1.03)^{-8} + \cdots + (1.03)^{-1}$.

26. Solve for n: $(1.05)^n = 6.325$.

27. Solve for n: $(1.045)^{-n} = 0.753$.

28. Find the rate of interest when, instead of paying $100 cash for an article, the purchaser pays $10 down and 10 monthly installments of $10 each.

29. A man buys a bill of goods amounting to $50. Instead of paying cash, he pays $5 down and 5 monthly installments of $10 each. Find the actual rate of interest paid.

30. On a cash bill for $150, $15 is paid down, followed by 10 monthly payments of $15 each. Find the rate of interest paid.

31. The cash price of an article is C. Instead of paying cash the purchaser makes a down payment D followed by monthly installments of R at the end of each month for n months. Show that the interest rate i is given by the formula

$$i = \frac{24(nR + D - C)}{n(2C - 2D - nR + R)}$$

if all amounts are focalized at the time of the last payment.

32. (a) Using formula (12) show that R at the end of each month for n months is equivalent to nR at $(n + 1)/2$ months.

(b) Using the data of Exercise 31 and the conclusion of (a), focalizing all amounts at $(n + 1)/2$ months, show that

$$i = \frac{24(nR + D - C)}{(n + 1)(C - D)}.$$

(c) Note that $(nR + D - C)$ is the *total carrying charge* and $(C - D)$ is the *unpaid balance*.

CHAPTER II

COMPOUND INTEREST AND COMPOUND DISCOUNT

14. Compound interest.—Simple interest is calculated on the original principal only, and is proportional to the time. Its chief value is its application to short-term loans and investments. Long-term financial operations are usually performed under the assumption that the interest, when due, is added to the principal and the interest for the next period of time is calculated on the principal thus increased, and this process is continued with each succeeding accumulation of interest. Interest when so computed is said to be *compound*. Interest may be compounded annually, semi-annually, quarterly, or at some other regular interval. That is, interest is converted into principal at these regular intervals. The time elapsing between successive periods, when the interest is converted into principal, is commonly defined as the *conversion period*. For example, if the interest is converted into principal semi-annually, the conversion period is six months. The rate of interest is nearly always expressed on an annual basis and if nothing is specified as to the conversion period, it is commonly assumed to be one year. The final amount at the end of the time, after all of the interest has been converted into principal, is defined as the *compound amount*. Consequently, *the compound interest is equal to the compound amount minus the original principal*.

Example. Find the compound amount and compound interest on $600 for four years at 5%, the interest being converted annually.

Solution. The interest for the first (conversion period) year is $600(0.05) = $30.00. When this is converted into principal, the amount at the end of the first year becomes $630. The interest for the second year is $630(0.05) = $31.50, and when this is converted the principal becomes $661.50. Continuing this process until the end of the fourth year, we find the compound amount to be $729.30; and the compound interest for the given time is $129.30, the difference between $729.30 and $600.

The solution of the above example can be written in the following form:

$$\text{Interest for first year} = \$600(0.05)$$
$$\text{Principal at end of first year} = \$600 + \$600(0.05)$$
$$= \$600(1 + 0.05) = \$600(1.05)$$
$$\text{Interest for second year} = \$600(1.05)\,(0.05)$$
$$\text{Principal at end of second year} = \$600(1.05) + \$600(1.05)\,(0.05)$$
$$= \$600(1.05)\,(1.05)$$
$$= \$600(1.05)^2$$
$$\text{Interest for third year} = \$600(1.05)^2(0.05)$$
$$\text{Principal at end of third year} = \$600(1.05)^2 + \$600(1.05)^2(0.05)$$
$$= \$600(1.05)^2(1.05)$$
$$= \$600(1.05)^3$$
$$\text{Interest for fourth year} = \$600(1.05)^3(0.05)$$
$$\text{Principal at end of fourth year} = \$600(1.05)^3 + \$600(1.05)^3(0.05)$$
$$= \$600(1.05)^3(1.05)$$
$$= \$600(1.05)^4$$
$$= \$600(1.21550625)$$
$$= \$729.30.$$

15. Compound interest formula.—If we let P be the original principal, i the **yearly rate of interest** and S the amount to which P will accumulate in n years and reason as in the illustrated example of Art. 14, we will obtain the compound interest formula.

The interest for the first year will be Pi and the principal at the end of the first year will be
$$P + Pi = P(1 + i).$$

The interest for the second year will be $Pi(1 + i)$ and the principal at the end of the second year will be

$$P(1 + i) + Pi(1 + i) = P(1 + i)^2.$$

By similar reasoning we find that the amount at the end of the third year is

$$P(1 + i)^2 + Pi(1 + i)^2 = P(1 + i)^3,$$

and in general the amount at the end of n years is $P(1 + i)^n$. Thus we have the formula

$$S = P (1 + i)^n. \tag{1}$$

This relation is easily visualized by the following line diagram:

$$P \qquad\qquad n \text{ years at } i\% \qquad\qquad S = P(1 + i)^n$$

compound interest

Example 1. Find the compound amount and compound interest on $500 for 8 years at 6%, the interest being converted annually.

Solution. Here, $P = \$500$, $i = 0.06$, $n = 8$.

Substituting in (1) we have

$$S = 500(1.06)^8.$$

From Table III, $\qquad (1.06)^8 = 1.59384807,$

and $\qquad\qquad S = 500(1.59384807) = \textbf{\$796.92.}$

The compound interest is

$$\$796.92 - \$500.00 = \$296.92.$$

Example 2. Find the compound amount on $850 for 12 years at 6¼%, the interest being converted annually.

Solution. Here, $P = \$850$, $i = 0.0625$, $n = 12$,

and $\qquad\qquad S = 850(1.0625)^{12}.$

We do not find the rate, 6¼%, in Table III, so we use logarithms to compute S.

$$\log 1.0625 = 0.02633$$

$$12 \log 1.0625 = 0.31596$$
$$\log 850 = 2.92942$$
$$\overline{\log S = 3.24538}$$
$$S = \$1,759.50.$$

Using a table of seven place logarithms we find $S = \$1,759.41$, which is correct to six significant digits. When we use a table of five place logarithms for computing, our results will be accurate to four and never more than five significant digits.

When P, n, and i are given, the *amount* S computed by (1) is frequently called the *accumulated value* of P at the end of n years. Hence, to *accumulate P* for n years at $i\%$ we find the amount S by using (1). The quantity $(1 + i)$ is called the *accumulation factor*.

Similarly, when S, n, and i are given, the *principal P* is called the *discounted* value of S due at the end of n years. Hence, to *discount S* for n years at $i\%$ we find the principal P by using (1). The principal P is also called the *present value* of S.

1. Find the amount of $1,000 invested 15 years at 4%.

2. Find the amount of $1,000 invested 12 years at 6%.

3. Accumulate $500 for 15 years at 6%.

4. Discount $800 for 20 years at 3%.

5. Find the difference between the amount of $100 at simple interest and at compound interest for 5 years at 5%.

6. At the birth of a son a father deposited $1,000 with a trust company that paid 4%, the fund accumulating until the son's twenty-first birthday. What amount did the son receive?

7. In the following line diagram each section represents 1 year. The point O denotes any given time. Any point to the right of O denotes a later time and any point to the left of O denotes an earlier time. Consider $100 at O. Based upon $i = 4\%$, what is its value at B? at A?

Solution. At B the value is that of $100 accumulated for 5 years, or $100(1 + .04)^5$. At A the value is that of $100 discounted for 4 years or $100(1 + .04)^{-4}$.
8. In the following line diagram, based upon $i = 5\%$, find the values at A, B, C, and D of $100 at O.

16. Nominal and effective rates of interest.—*The effective rate of interest is the actual interest earned on a principal of $1 in one year.* When interest is converted into principal more than once a year, the actual interest earned (effective rate) is more than the quoted rate (nominal rate). Thus, if we have a nominal rate of 6% and the interest is converted semi-annually, the effective rate is by a method similar to that used in Art. 14,

$$(1.03)^2 - 1 = 0.0609 = 6.09\%.$$

Then, on a principal of $10,000, a nominal rate of 6% convertible semi-annually gives in one year $609.00 interest.

Similarly, if the rate is 6%, convertible quarterly, the effective rate is

$$(1.015)^4 - 1 = 0.06136 = 6.136\%.$$

If we let i stand for effective rate, j for nominal rate, and m for the number of conversions per year, then $\dfrac{j}{m}$ will be the interest on $1 for one

conversion period. Hence, the amount of $1 at the end of one year will be given by

$$\left(1 + \frac{j}{m}\right)^m \tag{2}$$

and the effective rate will be given by the equation

$$i = \left(1 + \frac{j}{m}\right)^m - 1. \tag{3}$$

We may also write

$$(1 + i) = \left(1 + \frac{j}{m}\right)^m. \tag{4}$$

If $\left(1 + \frac{j}{m}\right)^m$ be substituted for $(1 + i)$ in (1), we obtain the equation

$$S = P\left(1 + \frac{j}{m}\right)^{mn}. \tag{5}$$

This equation gives the amount of a principal P *at the end of* n *years at rate* j *convertible* m *times per year.* If $m = 1$, (5) reduces to (1). Hence we say that (5) is the general compound interest formula and (1) is a special case of (5).

From (4), we may easily find j in terms of m and i. Extracting the mth root of each member and transposing, we find

$$j = m\,[(1 + i)^{1/m} - 1]. \tag{4'}$$

Sometimes the nominal rate j is written with a subscript to show the frequency of conversion in a year. Thus j_m means that the nominal rate is j with m conversion periods in a year. We also find it convenient at times to use the symbol "j_m at i" to mean "the nominal rate j which converted m times a year yields the effective rate i." Values of j for given values of m and i are found in Table IX.

Example 1. Find the effective rate corresponding to a nominal rate of 5% when the interest is converted quarterly.

Solution. Here, $j = 0.05$ and $m = 4$.

Substituting in (3), we have

$$i = (1.0125)^4 - 1$$
$$= (1.05094534) - 1 = 0.050945$$
$$= 5.0945\%.$$

Example 2. Find the amount of $750 for 15 years at 5% converted quarterly.

Solution. Here $P = \$750, j = 0.05, n = 15$ and $m = 4$. Substituting in (5) we have

$$S = 750(1.0125)^{60}.$$

From Table III, $(1.0125)^{60} = 2.10718135$,

and $\qquad\qquad S = 750(2.10718135) = \$1,580.39.$

Example 3. Find the compound amount of $500 for 120 years at 3%.

Solution. Here $P = \$500, i = 0.03, n = 120$. We find no value of $(1 + i)^n$ in the table when $n = 120$, but we may apply the index law, $a^x \cdot a^y = a^{x+y}$.

Hence, $(1.03)^{120} = (1.03)^{100} \cdot (1.03)^{20}$

$$= (19.21863198)(1.80611123)$$

$$= 34.710987$$

and $\qquad\qquad S = 500(34.710987) = \$17,355.49.$

This example illustrates a method by which the table can be used when the time extends beyond the table limit.

Example 4. To what sum does $5,000 amount in 7 years and 9 months at 4% converted semi-annually.

Solution. The given time contains 15 whole conversion periods and 3 months. Now, the compound amount at the end of the 15th period is

$$S = 5,000(1.02)^{15} = \$6,729.34.$$

The simple interest on $6,729.34 for the remaining 3 months is

$$6,729.34 \times \tfrac{3}{12} \times 0.04 = \$67.29.$$

Hence, the amount at the end of 7 years and 9 months is

$$\$6,729.34 + \$67.29 = \$6,796.63.$$

The solution of Example 4 illustrates a plan that is usually used for finding the compound amount when the time is not a whole number of conversion periods. We may state the plan as follows:

I. *Find the compound amount for the whole number of conversion periods, using (5).*

II. *Find the simple interest on the resulting amount at the given rate for the remaining time.*

III. *Add the results of I and II.*

Exercises

1. Find the amount of $800 invested for 8 years at 5%, convertible annually.

2. Solve Example 1, when the interest is converted (a) semi-annually, (b) quarterly. Use formula (5).

3. Find the compound interest on $2,500 at $6\frac{1}{2}\%$ for 8 years, if the interest is converted semi-annually.

4. A man pays $1,000 for a 10 year bond that is to yield 5%, payable semi-annually. What will be the amount of the original investment at the end of 10 years if the dividends are immediately reinvested at 5%, payable semi-annually?

5. On January 1, 1928, $1,500 was placed on time deposit at a certain bank. For 10 years the bank allowed 4% interest converted annually. During the next 4 years 3%, converted quarterly, was allowed, and on January 1, 1942 the interest rate allowed on such deposits was reduced to $2\frac{1}{2}\%$, converted semi-annually. What was the accumulated value of this original deposit as of January 1, 1945?

6. Find the effective rate equivalent to 6% nominal converted (a) semi-annually, (b) quarterly, (c) monthly.

7. A savings bank paid 5% compound interest on a certain deposit for 6 years and then 4% for the next 4 years. What single rate (equivalent rate) during the 10 years would have produced the same effect?

Solution.—Let i equal the equivalent rate.

$$\text{Then } (1 + i)^{10} = (1.05)^6 (1.04)^4.$$

$$
\begin{aligned}
\log 1.05 &= 0.0211893 \\
\log 1.04 &= 0.0170333 \\
\\
6 \log 1.05 &= 0.1271358 \\
4 \log 1.04 &= 0.0681332 \\
\hline
10 \log (1 + i) &= 0.1952690 \\
\log (1 + i) &= 0.0195269 \\
(1 + i) &= 1.04599 \\
i &= 0.04599 = 4.599\%.
\end{aligned}
$$

The value obtained for $(1 + i)$ is correct to six significant digits. A seven place table of logarithms was used here. When we use a table of seven place logarithms, we can be sure that our results are accurate to six significant digits.

8. What is the effective rate for 20 years equivalent to 6%, converted annually for the first 8 years; 5% converted semi-annually for the next 7 years; and 4%, converted quarterly for the last 5 years?

9. An individual has a sum of money to invest. He may buy saving certificates, paying $5\frac{1}{2}\%$ convertible semi-annually, or deposit it in a building and loan association, which pays 5% convertible monthly. Assuming that the degree of safety of the two is the same, should he buy the certificates or deposit his money in the association?

10. Find the compound amount on $750 for 8 years 9 months at 5% converted semi-annually.

11. Representing time along the horizontal axis and the computed values of S along the vertical axis, make graphs of $S = 100(1 + 0.04n)$ and $S = 100(1.04)^n$. Take for n the values 1, 5, 9, 13, 17, 21, 25 and use the same scale for both graphs.

12. Repeat Exercise 11, when the interest rate is 6%.

13. Accumulate $2,000 for 12 years if the interest rate is 5% compounded monthly.

14. A house is offered for sale. The terms are $4,000 cash, or $6,000 at the end of 10 years without interest. If money is worth 4%, interest converted semi-annually, which method of settlement is to the advantage of the purchaser?

15. Find the effective rate equivalent to 7% converted (a) monthly, (b) quarterly, (c) semi-annually.

16. Find the nominal rate, converted quarterly, that will yield an effective rate of (a) 4%; (b) 5%; (c) 6%.

17. Present value at compound interest.—In Art. 6 we defined the present value P of a sum S, due in n years, from the standpoint of simple interest. The definition of present value will be the same here, except that compound interest is used in the place of simple interest. From the definition of present value, it follows that the present value P of a sum S may be obtained by solving equation (1), Art. 15 for P. Solving this equation for P, we have

$$P = \frac{S}{(1 + i)^n} = S(1 + i)^{-n} = Sv^n, \text{ where } v = \frac{1}{1 + i}. \tag{6}$$

The number v is called the *discount factor*.

If the rate of interest is j, converted m times a year, we have from (5) Art. 16

$$P = \frac{S}{\left(1 + \dfrac{j}{m}\right)^{mn}} = S\left(1 + \dfrac{j}{m}\right)^{-mn}. \tag{7}$$

Compound discount is commonly defined as the future value S minus the present value P. If D stands for compound discount on S, we have

$$D = S - P. \tag{8}$$

Compare the above formula with (8), Art. 7.

Since P is defined as the principal that will accumulate to S, at compound interest, in n years, the difference $S - P$ also stands for the compound interest on P. Therefore, we may say that the compound discount on the accumulated value is the same as the compound interest on the present value for the given time at the specified interest rate.

Example 1. Find the present value and compound discount of $4,000 due in 10 years at 5% converted annually.

Solution. Here, $S = \$4,000$, $i = 0.05$, and $n = 10$.
Substituting in (6), we have

$$P = 4,000(1.05)^{-10}.$$

From Table IV, $(1.05)^{-10} = 0.61391325$

and $\qquad P = 4,000(0.61391325) = \$2,455.65.$

Also, $\qquad D = 4,000.00 - 2,455.65 = \$1,544.35.$

Example 2. Find the present value of $2,000 due in 8 years at 4¾% converted semi-annually.

Solution. Here, $S = \$2,000$, $j = 0.0475$, $m = 2$, and $n = 8$.
Substituting in (7), we have

$$P = 2,000(1.02375)^{-16}.$$

We do not find the rate, 2⅜%, in Table IV, so we use logarithms to compute S.

$$\log 1.02375 = 0.0101939$$
$$16 \log 1.02375 = 0.1631024$$

$$\log (1.02375)^{-16} = 9.8368976 - 10$$
$$\log 2,000 = 3.30103$$

$$\overline{\qquad\qquad \log P = 3.13793}$$
$$P = \$1,373.81.$$

Example 3. Find the present value of $5,000 due in 7 years with interest at 6% converted semi-annually, assuming money worth 5%.

Solution. We first find the maturity value of the debt and then find the present value of this sum.

Hence,
$$S = 5{,}000(1.03)^{14}$$
$$= 5{,}000(1.51258972)$$
$$= \$7{,}562.95,$$

and
$$P = S(1.05)^{-7}$$
$$= 7{,}562.95(1.05)^{-7}$$
$$= 7{,}562.95(0.71068133)$$
$$= \$5{,}374.86.$$

$5,000   int. at (j = .06, m = 2)   S = $7,562.95

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |

P   int. at i = .05 $7,562.95

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
This example illustrates a method for finding the present value of an interest-bearing debt.

Problems

1. What is the present value of a note of $200 due in 6 years without interest, assuming money worth 6%?

2. Find the present value of $3,000 due in 5 years, if the nominal rate is 5%, convertible semi-annually.

3. What sum of money invested now will amount to $4,693.94 in 25 years if the nominal rate is 5¾%, convertible semi-annually?

4. A note of $3,750 is due in 4½ years with interest at 6% payable semi-annually. Find its value 3 years before it is due, if at that time money is worth 5%.

5. What is the present value of a $1,000 note due in 5 years with interest at 8% payable semi-annually, when money is worth 6%?

6. Compare the present values of non-interest-bearing debts of $400 due in 3 years and $450 due in 5 years, assuming money worth 6% converted semi-annually. Compare the values of these debts 2 years from now, assuming that money is still worth 6% converted semi-annually.

7. An investment certificate matures in 3 years for $1,000. Its present cash value is $860. If one desires his money to earn 5% annually, should he purchase the certificate?

8. A debt of $4,500 will be due in 10 years. What sum must one deposit now in a trust fund, paying 4½% converted semi-annually, in order to pay the debt when it falls due?

9. What is the present value of $300, due in 4 years and 3 months without interest, when money is worth 5%?

10. A father wishes, at the birth of his son, to set aside a sum that will accumulate to $2,500 by the time the son is 21 years old. How much must be set aside, if it accumulates at 3% converted semi-annually?

11. Draw graphs of $P = \dfrac{S}{(1+i)^n}$ and $P = \dfrac{S}{1+ni}$ for integral values of n from 0 to 10. For convenience, take $S = 10$ and $i = 0.05$. Take values of n along the horizontal axis and corresponding values of P along the vertical axis, using the same scale and set of axes for both graphs. Use Table IV for finding the values of $P = \dfrac{S}{(1+i)^n}$.

12. If \$2,500 accumulates to \$3,700.61 in a certain time at a given rate, what is the present value of \$2,500 for the same time and rate?

13. Find the present value of a debt of \$250, due in 5 years 3 months and 15 days, if money is worth 5%.

14. An investment certificate matures in 7 years for \$500. If money is worth 4% for the first 3 years and $3\frac{1}{2}$% thereafter, what is the present value of the certificate?

15. A man desires to sell a house and receives two offers. One is for \$2,500 cash and \$5,000 in 5 years. The other is for \$3,000 cash and \$4,000 to be paid in 3 years. On a 5% basis, which is the better offer for the owner of the house and what is the difference between the two offers?

16. An insurance company allows $3\frac{1}{2}$% compound interest on all premiums paid one year or more in advance. A policy holder desires to pay in advance three annual premiums due in 1 year, 2 years, and 3 years respectively. How much must he pay the company now if each annual premium is \$21.97?

17. Making use of the binomial theorem (assuming n greater than 1) show that $(1+i)^n$ is greater than $(1+ni)$. Using Table III compare these values when $n = 5$ and $i = 0.06$.

18. Other problems solved by the compound interest formulas.— Formulas (1) and (5) each contain four letters (assuming m in (5) to be fixed). Any one of these letters can be expressed in terms of the other three. In Art. 16 we solved problems in which S was the unknown and in Art. 17 we solved for P. We shall now solve some problems when the value of n or j is required.

Example 1. In how many years will \$742.33 amount to \$1,000 if invested at 6%, converted quarterly?

Solution. From (5), Art. 16, we have

$$1{,}000 = 742.33(1.015)^{4n}.$$

Taking logarithms of both members of the above equation, we get

$$\log 1{,}000 = \log(742.33) + 4n \log(1.015).$$

Solving for n,

$$n = \frac{\log(1,000) - \log(742.33)}{4 \log(1.015)} = \frac{3.00000 - 2.87060}{4(0.00647)}$$

$$= \frac{0.12940}{0.02588} = 5.$$

Hence, \$742.33 will amount to \$1,000 in 5 years, if the rate is 6% converted quarterly.

Example 2. How long will it take \$1,000 to amount to \$1,500 at 5% converted semi-annually?

Solution. Substituting in (5), Art. 16, we have

$$1,500 = 1,000(1.025)^{2n}.$$

The above equation reduces to

$$(1.025)^{2n} = 1.5.$$

From the 2½% column in Table III, we find that $(1.025)^{2n} = 1.4845\ 0562$ when $2n = 16$; and when $2n = 17$, $(1.025)^{2n} = 1.5216\ 1826$. The nearest time, then, is 16 semi-annual periods or 8 years. That is, \$1,000 amounts to \$1,484.51 in 8 years at 5% converted semi-annually. We now find the time required for \$1,484.51 to amount to \$1,500 at 5% simple interest. Here, $P = \$1,484.51$, $I = \$15.49$, and $i = 0.05$. We solve for n as in illustrated Example 4, Art. 70.

$$n = \frac{15.49}{(1,484.51)\,(0.05)} = \frac{15.49}{74.2255}$$

$$= 0.209 \text{ year (approximately), or 2 months and}$$
$$\text{15 days.}$$

Hence, we find that \$1,000 will amount to \$1,500 in 8 years 2 months and 15 days at 5% converted semi-annually.

Examples 1 and 2 illustrate methods for finding n, when S, P, and i are given.

Example 3. At what rate would \$2,500 amount to \$5,000 in 14 years if interest were converted semi-annually?

Solution. From (5), Art. 16, we have

$$5,000 = 2,500\left(1 + \frac{j}{2}\right)^{28}.$$

Taking logarithms of both members of the above equation, we get

$$\log 5{,}000 = \log 2{,}500 + 28 \log\left(1 + \frac{j}{2}\right),$$

$$\log\left(1 + \frac{j}{2}\right) = \frac{\log 5{,}000 - \log 2{,}500}{28}$$

$$= \frac{3.69897 - 3.39794}{28} = \frac{0.30103}{28}$$

$$= 0.01075.$$

$$\left(1 + \frac{j}{2}\right) = 1.025$$

$$\frac{j}{2} = 0.025$$

$$j = 0.05 = 5\%.$$

That is, the rate is 5% nominal, convertible semi-annually. From (4) Art. 16 we find the effective rate to be $i = 5.0625\%$.

Example 4. At what rate would $1,500 amount to $2,500 in 9 years, if the interest were converted annually?

Solution. From (1), Art. 15, we have

$$2{,}500 = 1{,}500(1 + i)^9.$$

Dividing the above equation through by 1,500, we get

$$(1 + i)^9 = 1.6667 \text{ (to 4 decimal places)}.$$

In Table III we notice that when $i = 0.055$, $(1 + i)^9 = 1.6191$; when $i = 0.06$, $(1 + i)^9 = 1.6895$. Hence, i is a rate between 5½% and 6%.

By interpolation, we find

$$i = 0.055 + (0.005)\,(^{476}\!/_{704})$$

$$= 0.055 + 0.00338 = 0.05838.$$

Hence, the rate is 5.84% (approximately). The student should also solve this example by logarithms.

Examples 3 and 4 illustrate methods for finding the rate when S, P, and n are given.

1. In what time will $840 accumulate to $2,500 at 5%, converted annually?

2. If $1,000 is invested in securities and amounts to $2,500 in 15 years, what is the average annual rate of increase?

3. At what rate must $10,000 be invested to become $35,000 in 25 years?

4. In how many years will $400 amount to $873.15 at 5% annually?

5. How long will it require any sum to double itself at effective rate i?

6. How long will it require a principal to double itself at (a) 5%, (b) 6%?

7. How long will it take $1,500 to amount to $5,000 at 6% converted quarterly?

8. At what rate will $2,000 amount in 30 years to $10,184.50 if the interest is converted semi-annually?

9. A will provides that $15,000 be left to a boy to be held in trust until it amounts to $25,000. When will the boy receive the fund if invested at 4% converted semi-annually?

10. A man invested $1,500 in securities and re-invested the dividends from time to time and at the end of 10 years he found that his investments had accumulated to $2,700. What was his average rate of interest?

19. Equation of value.—In Art. 11 the equation of value was defined and used in connection with simple interest. The *equation of value* used here will have the same meaning as in Art. 11. That is, it is the equation that expresses the equivalence of two sets of obligations on a common date (focal date). In Art. 11 we assumed, for convenience, that the equation of value is true for any focal date. However, this assumption is only approximately true, as was pointed out by a particular example. That is, when simple interest is used the equivalence of two sets of obligations actually depends upon the focal date selected. *The equivalence of two sets of sums, however, is independent of the focal date when the sums are accumulated* or *discounted by compound interest.* That is, if we have an equation of value for a certain focal date, we may obtain an equation of value for any other focal date by multiplying or dividing the first equation through by some power of $(1 + i)$ or of $(1 + j/m)$.

Example 1. *A* owes *B* the following debts: $300 due in 3 years without interest and $700 due in 8 years without interest. *B* agrees that *A* may settle the two obligations by making a single payment at the end of 5 years. If the two individuals agree upon 6% as a rate of interest, find the single payment.

Solution. Let x stand for the single payment, and choose 5 years from now as the focal date.

The $300 debt is due 2 years before the focal date and amounts to $300(1.06)^2$ on the focal date.

The $700 debt is due 3 years after the focal date and has a value of $700(1.06)^{-3}$ on the focal date.

The single payment x is to be made on the focal date and has a value of x on that date.
Then, for the equation of value, we have

$$x = 300(1.06)^2 + 700(1.06)^{-3}$$

$$= 300(1.12360000) + 700(0.83961928)$$

$$= 337.08 + 587.73$$

$$= 924.81.$$

Hence, the two debts may be discharged by a single payment of **$924.81** five years from now.

Had we assumed 8 years from now as focal date, our equation of value would have been

$$x(1.06)^3 = 300(1.06)^5 + 700.$$

Dividing the above equation through by $(1.06)^3$, we get

$$x = 300(1.06)^2 + 700(1.06)^{-3},$$

which is the equation of value obtained when 5 years from now is taken as the focal date. This is an illustration of the fact that an equation of value does not depend upon our choice of a focal date.

The student will observe that in the construction of the line diagram we place at the respective points the **maturity values** of the debts. Further, it should be observed that the payment and the debts are placed at different levels.

Example 2. Smith owes Jones $500 due in 4 years with interest at 5% and $700 due in 10 years with interest at $4\frac{1}{2}\%$. It is agreed that the two debts be settled by paying $600 at the end of 3 years and the balance at the end of 8 years. Find the amount of the final payment, assuming an interest rate of $5\frac{1}{2}\%$.

Solution. Let x stand for the final payment and choose 8 years from now as the focal date.

The maturity value of the \$500 debt is $500(1.05)^4$ and its value on the focal date is $500(1.05)^4(1.055)^4$.

The maturity value of the \$700 debt is $700(1.045)^{10}$ and its value on the focal date is $700(1.045)^{10}(1.055)^{-2}$.

The value of the \$600 payment is $600(1.055)^5$ on the focal date.

The value of the final payment is x on the focal date.
Expressing the fact that the value of the payments equals the value of the debts (on the focal date), our equation of value becomes

$$600(1.055)^5 + x = 500(1.05)^4(1.055)^4 + 700(1.045)^{10}(1.055)^{-2}.$$

Making use of Tables III and IV and performing the indicated multiplications, we have

$$784.176 + x = 752.900 + 976.688$$

and

$$x = 945.41.$$

Hence, the payment to be made 8 years from now is \$945.41.

20. Equated time.—In Art. 12 *equated time* was discussed and a formula (based upon simple interest) for finding this time was developed. Basing our discussion on compound interest, we shall now solve a particular example and then consider the general problem, thereby developing a formula.

Example 1. Find the time when debts of \$1,000 due in 3 years without interest and \$2,000 due in 5 years with interest at 5% may be settled by a single payment of \$3,000, assuming an interest rate of 6%.

Solution. Choose "now" as the focal date and let x stand for the time in years, measured from the focal date ("now"), until the single payment of \$3,000 should be made. Our equation of value becomes

$$3,000(1.06)^{-x} = 1,000(1.06)^{-3} + 2,000(1.05)^5(1.06)^{-5}$$

$$3,000(1.06)^{-x} = 1,000(0.83962) + 2,000(1.27628)(0.74726),$$

$$3,000(1.06)^{-x} = 839.62 + 1,907.43 = 2,747.05,$$

$$(1.06)^{-x} = \frac{2,747.05}{3,000.00},$$

$$(1.06)^x = \frac{3,000}{2,747.05},$$

$$x \log 1.06 = \log 3,000 - \log 2,747.05,$$

$$x = \frac{\log 3,000 - \log 2,747.05}{\log 1.06}$$

$$= \frac{3.47712 - 3.43886}{0.02531} = 1.51.$$

Hence, the two debts may be settled by a single sum of \$3,000 in 1 year, 6 months from "now."

Problem. Given that A owes B debts of $D_1, D_2, D_3, \cdots$ having maturity values of $S_1, S_2, S_3, \cdots$ and due in $n_1, n_2, n_3, \cdots$ years respectively. Assuming an interest rate of $i\%$, find the time when the debts may be settled by making a single payment of $S = S_1 + S_2 + S_3 + \cdots$.

Solution. Choose "now" as the focal date and let n stand for the time in years, measured from the focal date (now), until the single payment of S should be made.

Reasoning as in Example 1, the equation of value becomes

$$(S_1 + S_2 + S_3 + \cdots)(1 + i)^{-n}$$
$$= S_1(1 + i)^{-n_1} + S_2(1 + i)^{-n_2} + S_3(1 + i)^{-n_3} + \cdots. \quad (9)$$

Solving the above equation for $(1 + i)^{-n}$, we get

$$(1 + i)^{-n} = \frac{S_1(1 + i)^{-n_1} + S_2(1 + i)^{-n_2} + S_3(1 + i)^{-n_3} + \cdots}{S_1 + S_2 + S_3 + \cdots}$$

and

$$(1 + i)^n = \frac{S_1 + S_2 + S_3 + \cdots}{S_1(1 + i)^{-n_1} + S_2(1 + i)^{-n_2} + S_3(1 + i)^{-n_3} + \cdots}.$$

Taking logarithms of both sides of the above equation and solving for n, we have

$$n = \frac{\log(S_1 + S_2 + S_3 + \cdots) - \log[S_1(1+i)^{-n_1} + S_2(1+i)^{-n_2} + S_3(1+i)^{-n_3} + \cdots]}{\log(1 + i)}.$$

$$(10)$$

Formula (10) gives the exact value for the equated time. However, it is obviously very involved and is rather tedious to apply. We naturally seek a satisfactory approximation formula. We shall now proceed to find one.

If $(1 + i)^{-n}$ is expanded by the binomial theorem, we have

$$(1 + i)^{-n} = 1 - ni + \frac{n(n + 1)}{2} i^2 - \frac{n(n + 1)(n + 2)}{2 \cdot 3} i^3 + \cdots.$$

Neglecting all powers of i higher than the first gives $(1 - ni)$ as an approximate value of $(1 + i)^{-n}$.

Applying the binomial theorem to $(1 + i)^{-n_1}$, $(1 + i)^{-n_2}$, $\cdots$ and dropping powers of i higher than the first, we obtain $(1 - n_1 i)$, $(1 - n_2 i)$, $\cdots$ as approximate values of $(1 + i)^{-n_1}$, $(1 + i)^{-n_2}$, $\cdots$ respectively.

If in (9), $(1 + i)^{-n}$ and $(1 + i)^{-n_1}$, $(1 + i)^{-n_2}$, $\cdots$ are replaced by their approximate values, we get, on solving for n,

$$n = \frac{n_1 S_1 + n_2 S_2 + n_3 S_3 + \cdots}{S_1 + S_2 + S_3 + \cdots}. \tag{11}$$

Now, if the original debts, D_1, D_2, D_3, $\cdots$ are non-interest-bearing, S_1 S_2, S_3, $\cdots$, may be replaced by D_1, D_2, D_3, $\cdots$, respectively, and the above equation becomes

$$n = \frac{n_1 D_1 + n_2 D_2 + n_3 D_3 + \cdots}{D_1 + D_2 + D_3 + \cdots}. \tag{11'}$$

We notice that (11) is essentially the same as (12), Art. 12. When the periods of time involved are short and the debts, D_1, D_2, D_3, $\cdots$ do not draw interest, (11') gives us a close approximation of the equated time. However, when the periods of time are short and the debts D_1, D_2, D_3, $\cdots$ draw interest (11) gives a good approximation to n.

Example 2. Find the equated time for paying in one sum debts of $300 due in 3 years and $150 due in 5 years.

Solution. Choosing "now" as focal date and substituting in (11'), we have

$$n = \frac{(300)3 + (150)5}{300 + 150} = 3.67 \text{ years.}$$

Assuming an interest rate of 6% and applying (10), we find

$$n = \frac{\log 450 - \log [300(1.06)^{-3} + 150(1.06)^{-5}]}{\log 1.06}$$

$$= \frac{2.65321 - 2.56118}{0.02531} = \frac{0.09203}{0.02531} = 3.64 \text{ years.}$$

We notice that the results by the two methods differ by only 0.03 of a year or about 11 days.

21. Compound discount at a discount rate.—In Art. 17 we defined the compound discount on the sum S as $S - P$, the difference between S and its present value P. The present value P has been found at the effective rate $i\%$ and at the nominal rate (j, m) to be

$$P = S(1 + i)^{-n} = S(1 + j/m)^{-mn}.$$

We may also find the present value P for a given discount rate. If the discount rate is d convertible annually, we have from (10) Art. 9 that $d = i/(1 + i)$ and $1 + i = 1/(1 - d)$. Hence we have

$$P = S(1 + i)^{-n} = S(1 - d)^n \qquad (12)$$

as the present value of a sum S due in n years at the effective discount rate d. The compound discount on S is

$$D = S - P = S - S(1 - d)^n = S[1 - (1 - d)^n]. \qquad (13)$$

If the discount is converted m times a year at the nominal rate f, the corresponding effective rate is the discount on \$1 in 1 year. We shall find the relation between d and f.

```
(1 - f/m)^m                                              1
 •————————•————————•————————•  ·  ·  ·  ·  ·  ·  •————————•
 0        1        2        3  ·  ·  ·  ·  ·  m - 1    m periods
```
Consider \$1 due at the end of 1 year (m conversion periods). Its value at the end of the first discount period is $1 - f/m$. Its value at the end of the second discount period is $(1 - f/m)^2$, and at the end of the mth discount period, that is at the beginning of the year, is $(1 - f/m)^m$. But by Art. 7 its present value is $1 - d$. Therefore, we have

$$1 - d = (1 - f/m)^m \qquad (14)$$

as the equation that expresses the relation between the nominal and

effective rates of discount. This is similar to (4) Art. 16, which shows the relation between the nominal and effective rates of interest.

Further, we have upon substituting in (12)

$$P = S(1 - d)^n = S(1 - f/m)^{mn} \tag{15}$$

as the present value of a sum S due in n years discounted at a nominal rate of discount f convertible m times a year. Immediately we have the corresponding compound discount

$$D = S - P = S[1 - (1 - f/m)^{mn}]. \tag{16}$$

22. Summary of interest and discount.—Let P be the principal and

S be the accumulated value or amount of P at the end of n years. Then:

I. Simple interest and discount.

   1. At simple interest rate i:

$$P = \frac{S}{1 + ni} \qquad\qquad S = P(1 + ni).$$

   2. At simple discount rate d:

$$P = S(1 - nd) \qquad S = \frac{P}{1 - nd}.$$

In each case

   3. $S - P =$ simple interest on P for n years.

$$= \text{simple discount on } S \text{ for } n \text{ years.}$$

Combining 1 and 2 we obtain

   4. $\qquad i = \dfrac{d}{1 - nd} \qquad\qquad d = \dfrac{i}{1 + ni}.$

II. Compound interest and discount.

   1. At effective rate of interest i:

$$P = S(1 + i)^{-n} \qquad S = P(1 + i)^n.$$

   2. At nominal rate of interest (j,m):

$$P = S(1 + j/m)^{-mn} \qquad S = P(1 + j/m)^{mn}.$$

3. At effective rate of discount d:

$$P = S(1 - d)^n \qquad S = P(1 - d)^{-n}.$$

4. At nominal rate of discount (f,m):

$$P = S(1 - f/m)^{mn} \qquad S = P(1 - f/m)^{-mn}.$$

Combining 1 and 2 we obtain

5. $$1 + i = (1 + j/m)^m.$$

Combining 3 and 4 we obtain

6. $$1 - d = (1 - f/m)^m.$$

In each case

7. $S - P =$ compound interest on P for n years.

$\qquad =$ compound discount on S for n years.

Problems

1. A debt of $1,500 is due without interest in 5 years. Assuming an interest rate of 5%, find the value of the debt (a) now, (b) in 3 years, (c) in 6 years.

2. Solve Problem 1, assuming that the debt draws 6% interest convertible semi-annually.

3. A debt of $500, drawing 6% interest will be due in 4 years. Another debt of $750, without interest will be due in 7 years. Assuming money worth 5%, compare the debts (a) now, (b) 4 years from now, (c) 6 years from now.

4. Set up the equation of value for Example 2, Art. 19, assuming now as the focal date and show that the equation is equivalent to the one used in the solution of the example.

5. A person is offered $2,500 cash and $1,500 at the end of each year for 2 years. He has a second offer of $3,100 cash and $800 at the end of each year for 3 years. Assuming that money is worth 6% to him, which offer should he accept?

6. A owes B debts of $1,000 due at the end of each year for 3 years without interest. A desires to settle with B in full now and B agrees to accept settlement under the assumption that money is worth 5%. How much does A pay to B?

7. (a) In Problem 6 find the value of the debts 3 years from now, assuming 5% interest. (b) Also, find the present value of this result, assuming money worth 5%. (c) How does the result of (b) compare with the answer to Problem 6? Explain your results.

8. Smith owes Jones $1,000 due in 2 years without interest. Smith desires to discharge his obligation to Jones by making equal payments at the end of each year for 3 years. They agree on an interest rate of 6%. Find the amount of each payment.

9. A man owes $600 due in 4 years and $1,000 due in 5 years. He desires to settle these debts by paying $850 at the end of 3 years and the balance at the end of 6 years. Assuming money worth 6%, find the amount of the payment to be made at the end of 6 years.

10. Solve Problem 9, assuming that the debts draw 5% interest.

11. A man owes $2,000 due in 2 years and $3,000 due in 5 years, both debts with interest at 5%. Find the time when the two obligations may be paid in a single sum of $5,000, if money is worth 6%, converted semi-annually.

12. *A* owes *B* $200 due now, $300 due in 2 years without interest, and $500 due in 3 years with 4% interest. What sum will discharge the three obligations at the end of $1\frac{1}{2}$ years if money is worth 6%, converted semi-annually?

13. There are three debts of $500, $1,000, and $2,000 due in 3 years, 5 years and 7 years respectively, without interest. Find the time when the three obligations could be paid in a single sum of $3,500, money being worth 5%.

14. Solve Problem 13, making use of the approximate formula, (11′).

15. Money being worth 6%, find the equated time for paying in one sum the following debts: $400 due in 2 years, $600 due in 3 years, $800 due in 4 years and $1,000 due in 5 years. Choose 2 years from now as focal date and set up an equation of value as in Example 1, Art. 12. Check the results by making use of the approximate formula.

16. Assuming money worth 5% show that $500 now is equivalent to $670.05 six years from now. Compare these two values on a 6% interest basis.

17. Show that:

$$\text{a. } \frac{j}{m} = \frac{\dfrac{f}{m}}{1 - \dfrac{f}{m}}, \quad \text{b. } \frac{f^{\,\urcorner}}{m} = \frac{\dfrac{j}{m}}{1 + \dfrac{j}{m}}. \tag{17}$$

18. Find the values of $(j, 2)$ and $(f, 2)$ that correspond to $i = 0.06$.

19. A money lender charges 3% a month paid in advance for loans. What is the corresponding nominal rate of interest? What is the effective rate?

20. I purchase from the Jones Lumber Company building material amounting to $1,000. Their terms are "net 60 days, or 2% off for cash." What is the highest rate of interest I can afford to pay to borrow money so as to pay cash?

21. If a merchant's money invested in business yields him 2% a month, what discount rate can he afford to grant for the immediate payment of a bill on which he quotes "net 30 days"?

22. Find the nominal rate of interest convertible quarterly that is equivalent to $(j = .06, m = 2)$.

Hint. The two nominal rates are equivalent if they produce the same effective rate. Let i represent this common effective rate. Then $1 + i = (1 + .03)^2 = (1 + j/4)^4$.

23. Find the nominal rate of interest convertible semi-annually that is equivalent to $(j = .06, m = 4)$.

24. If $2,350 amounts to $3,500 in $4\frac{3}{4}$ years at the nominal rate $(j, 4)$, find j. Solve (a) by interpolation, and (b) by logarithms.

25. How long will it take a sum of money to double itself at (a) $i = .06$, (b) $(j = .06, m = 2)$, (c) $(j = .04, m = 2)$?

26. A man bought a house for $4,000 and sold it in 8 years for $7,000. What interest rate did he earn on his investment?

CHAPTER III

ANNUITIES CERTAIN

23. Definitions.—An *annuity* is a sequence of equal payments made at equal intervals of time. Strictly speaking, the word "annuity" implies yearly payments, but it is now understood to apply to all equal periodic payments, whether made annually, semi-annually, quarterly, monthly, weekly, or otherwise. Typical examples of annuities are: monthly rent on property, monthly wage of an individual, premiums for life insurance, dividends on bonds, and sinking funds.

An *annuity certain* is one whose payments extend over a fixed number of years. A *contingent annuity* is one whose payments depend upon the happening of some event whose occurrence cannot be accurately foretold. The payments on a life insurance policy constitute a contingent annuity. In this chapter we shall be concerned entirely with annuities certain.

The time between successive payments is called the *payment period*. The time from the beginning of the first payment period to the end of the last payment period is called the *term* of the annuity.

Annuities certain may be classified into three groups: *Ordinary annuities, annuities due,* and *deferred annuities.* An *ordinary annuity* is one whose first payment is made at the *end* of the first payment period. If the first payment is made at the *beginning* of the first payment period, the annuity is called an *annuity due.* If the term of the annuity is not to begin until some time in the future, the annuity is called a *deferred annuity.*

The periodic payment into an annuity is frequently called the *periodic rent.* The sum of the payments of the annuity which occur in a year is called the *annual rent.*

Illustration. A sequence of payments of $100 each, at the end of each quarter for 3 years, constitutes an annuity whose payment period is one-fourth of a year. The term begins immediately (one quarter before the first payment) and ends at the close of three years. The periodic rent is $100 and the annual rent is 4($100), or $400. This annuity is pictured in the line diagram.
There are four general cases of ordinary annuities to which we shall give especial consideration. They are briefly described by the outline:

A. Annuity payable annually.

    I. Interest at effective rate i.

    II. Interest at nominal rate (j, m).

B. Annuity payable p times a year.

    I. Interest at effective rate i.

    II. Interest at nominal rate (j, m).

A. ANNUITY PAYABLE ANNUALLY

24. Amount of an annuity.—*The sum to which the total number of payments of the annuity accumulate at the end of the term is called the amount, or the accumulated value, of the annuity.* We shall illustrate.

Example 1. $100 is deposited in a savings bank at the end of each year for 4 years. If it accumulates at 5% converted annually, what is the total amount on deposit at the end of 4 years?

Solution. Consider the line diagram.
It is evident that the first payment will accumulate for 3 years. Hence its amount at the end of 4 years will be $\$100(1.05)^3$.

The second payment will accumulate for two years, and its amount will be $\$100(1.05)^2$, and so on.

Hence, the total amount at the end of 4 years will be given by

$$\$100(1.05)^3 + \$100(1.05)^2 + \$100(1.05) + \$100$$

or $\qquad \$100 + \$100(1.05) + \$100(1.05)^2 + \$100(1.05)^3. \qquad (1)$

We may compute the above products by means of the compound interest formula; their sum will be the amount on deposit at the end of 4 years. However, we notice that (1) is a geometric progression, having 100 for the first term, (1.05) for the ratio, and 4 for the number of terms.

Therefore, $\qquad\qquad$ Amount $= \dfrac{100[(1.05)^4 - 1]}{.05}. \qquad (2)$

Evaluating (2) by means of Table III, we have

$$\frac{100[(1.05)^4 - 1]}{.05} = \frac{100(1.2155062 - 1)}{.05} = 431.01.$$

Hence, the amount of the above annuity is \$431.01.

The arithmetical solution of the above example may be tabulated as follows:

End of Year	Annual Deposit	Interest	Total Increase in Deposit	Total on Deposit
1	\$100.00	......	\$100.00	\$100.00
2	100.00	\$ 5.00	105.00	205.00
3	100.00	10.25	110.25	315.25
4	100.00	15.76	115.76	431.01
Totals	\$400.00	\$31.01	\$431.01	

We shall now find the amount of an annuity of \$1 per annum for n years at an effective rate i. The symbol $s_{\overline{n}|i}$ is used to represent the amount of an annuity of 1 per annum payable annually for n years at the effective rate i. The first payment of 1 made at the end of the first year will be at interest for $n - 1$ years and will accumulate to $(1 + i)^{n-1}$.

The second payment of 1 will be at interest for $n - 2$ years and will accumulate to $(1 + i)^{n-2}$.

The third payment of 1 will be at interest for $n - 3$ years and will accumulate to $(1 + i)^{n-3}$, and so on.

The last payment will be a cash payment of 1. We have then

$$s_{\overline{n}|i} = (1 + i)^{n-1} + (1 + i)^{n-2} + (1 + i)^{n-3} + \ldots + (1 + i) + 1$$

$$= 1 + (1 + i) + (1 + i)^2 + \ldots + (1 + i)^{n-2} + (1 + i)^{n-1}. \quad (3)$$

This is a geometric progression of n terms, having 1 for first term and $(1 + i)$ for ratio. Finding the sum (*Alg.: Com.—Stat.*,* Art. 60), we have †

$$s_{\overline{n}|i} = \frac{(1 + i)^n - 1}{i}. \quad (4)$$

If the annual rent is R and if S represents the amount, we have

$$S = R \cdot s_{\overline{n}|i} = R \frac{(1 + i)^n - 1}{i}. \quad (5)$$

* When it is not desired to emphasize the interest rate, this symbol is frequently written $s_{\overline{n}|}$.

† See page x of this text for a list of formulas from *Alg.: Com.—Stat.*

Example 2. Find the amount of an annuity of \$200 per annum for 10 years at 5% converted annually.

Solution. Here, $R = \$200$, $n = 10$, and $i = 0.05$. Substituting in (5), we get

$$S = 200 \cdot s_{\overline{10}|.05} = 200\,\frac{(1.05)^{10} - 1}{0.05}.$$

In Table V we find the amount of an annuity of 1 per period for n periods at rate i per period.

When $n = 10$ and $i = 0.05$, we find

$$s_{\overline{10}|.05} = \frac{(1.05)^{10} - 1}{0.05} = 12.57789254$$

and

$$S = 200(12.57789254) = 2515.58.$$

Hence, the amount of the annuity is \$2515.58.

<center>**Exercises**</center>

Find the amount of the following annuities:

1. \$300 per year for 10 years at 4% interest converted annually.

2. \$500 per year for 20 years at 5% converted annually.

3. \$200 per year for 6 years at 3% converted annually. Make a schedule showing the yearly increases and the amount of the annuity at the end of each year.

4. \$150 per year for 10 years at 6% converted annually.

5. In order to provide for the college education of his son, a father deposited \$100 at the end of each year for 18 years with a trust company that paid 4% effective. If the first deposit was made when the son was one year old, what was the accumulated value of all the deposits when the son was 18 years old?

6. A corporation sets aside \$3,700 annually in a depreciation fund which accumulates at 5%. What amount will be in the fund at the end of 15 years?

7. Write series (3) in the summation notation. (*Alg.: Com.—Stat.*, Art. 63.)

8. If \$1,000 is deposited at the end of each year for 10 years in a fund which is accumulated at 4% effective, what is the amount in the fund 4 years after the last deposit?

9. To create a fund of \$5,000 at the end of 10 years, what must a man deposit at the end of each year for the next 10 years if the deposits accumulate at 4% effective?

10. One man places \$4,000 at interest for 10 years; another deposits \$500 a year in the same bank for 10 years. Which has the greater sum at the end of the term if interest is at 4% effective?

Let us now find the amount of an annuity where the payments are made annually but the interest is converted more than once a year. We shall illustrate by an example.

Example 3. $100 is deposited in a savings bank at the end of each year for 4 years. If it accumulates at 5% converted semi-annually, what is the total amount on deposit at the end of 4 years?

Solution. Consider the line diagram.
It is evident that the first deposit will accumulate for 3 years and at the end of 4 years, ((5), Art. 16), will amount to $100(1.025)^6$.

The second payment will amount to $100(1.025)^4$, and so on.

Hence, the total amount at the end of 4 years will be given by

$$\$100(1.025)^6 + \$100(1.025)^4 + \$100(1.025)^2 + \$100$$

or

$$\$100 + \$100(1.025)^2 + \$100(1.025)^4 + \$100(1.025)^6. \qquad (6)$$

We notice that (6) is a geometrical progression, having 100 for the first term, $(1.025)^2$ for ratio, and 4 for the number of terms. Substituting in (8) Art. 60, *Alg.: Com.—Stat.*, we have

$$S = \text{Amount} = \frac{100[(1.025)^8 - 1]}{(1.025)^2 - 1}. \qquad (7)$$

It is evident that Table V cannot be used here, but we may use Table III.

Thus,

$$S = \frac{100(1.21840290 - 1)}{1.05062500 - 1}$$

$$S = \frac{100(0.2184029)}{0.050625} = 431.41.$$

By writing (7) in the form

$$S = 100 \cdot \frac{(1.025)^8 - 1}{.025} \cdot \frac{.025}{(1.025)^2 - 1},$$

we can identify the last two terms in the product as $s_{\overline{8}|.025}$ and $1/s_{\overline{2}|.025}$. Then

$$S = 100 \cdot s_{\overline{8}|.025} \cdot \frac{1}{s_{\overline{2}|.025}}$$

$$= 100(8.7361\ 1590) \cdot \frac{1}{2.025} = 431.41$$

as was obtained by the first method.

Hence, the amount of the annuity is $431.41.

The arithmetical solution of the above example may be tabulated as follows:

End of Year	Annual Deposit	Interest	Total Increase in Deposit	Total on Deposit
½				
1	$100.00	......	$100.00	$100.00
1½	......	$2.50	2.50	102.50
2	100.00	2.56	102.56	205.06
2½	......	5.13	5.13	210.19
3	100.00	5.25	105.25	315.44
3½	......	7.89	7.89	323.33
4	100.00	8.08	108.08	431.41

We notice that the amount in Example 3 is 40 cents more than the amount in Example 1. This is due to the fact that the interest is converted semi-annually in Example 3 and only annually in Example 1.

If the interest is converted m times per year, we may substitute, [(4) Art. 16], $\left(1 + \dfrac{j}{m}\right)^m$ for $(1 + i)$ and $\left(1 + \dfrac{j}{m}\right)^m - 1$ for i in (5) and obtain

$$S = R \frac{\left(1 + \dfrac{j}{m}\right)^{mn} - 1}{\left(1 + \dfrac{j}{m}\right)^m - 1}. \tag{8}$$

We can transform (8) into a form involving the annuity symbol $s_{\overline{n}|}$ by writing it in the form

$$S = R \frac{\left(1 + \dfrac{j}{m}\right)^{mn} - 1}{\dfrac{j}{m}} \cdot \frac{\dfrac{j}{m}}{\left(1 + \dfrac{j}{m}\right)^m - 1}$$

$$= R \cdot s_{\overline{mn}|\frac{j}{m}} \cdot \frac{1}{s_{\overline{m}|\frac{j}{m}}} \tag{8a}$$

Example 4. Find the amount of $200 per annum for 10 years at 5% converted quarterly.

Solution. Here, $R = \$200$, $n = 10$, $j = 0.05$, and $m = 4$. Substituting in (8a), we have

$$S = 200. \quad s_{\overline{40}|.0125} \cdot \frac{1}{s_{\overline{4}|.0125}}$$

$$= 200(51.4895\ 5708) \cdot \frac{1}{4.0756\ 2695}$$

$$= 2{,}526.71$$

Hence the amount is \$2,526.71.

Why is the amount in Example 4 greater than the amount in Example 2?

Exercises

Find the amount of the following annuities:

1. \$300 per year for 8 years at 6% interest, converted semi-annually.

2. \$250 per year for 25 years at 5% converted quarterly.

3. \$500 per year for 5 years 4% converted semi-annually. Make a schedule showing the increases each six months and the amount of the annuity at the end of each six months.

4. \$600 per year for 30 years at $4\frac{1}{2}$% converted semi-annually.

5. \$750 per year for 15 years at 4.2% converted semi-annually. (Hint: Use logarithms to evaluate $(1.021)^{30}$.)

6. On the first birthday of his son a father deposits \$100 in a savings bank paying $3\frac{1}{2}$% interest, converted semi-annually. If he deposits a like amount on each birthday until the son is 21 years old, how much will be on deposit at that time?

7. A man deposits \$1,000 at the end of each year in a bank that pays 4% effective. Another man deposits \$1,000 at the end of each year in a bank that pays ($j = .035$, $m = 2$). At the end of 10 years how much more does the first man have than the second?

8. A man deposited \$1,000 a year in a bank. At the end of 15 years he had \$19,000.00 to his credit. What effective rate of interest did he receive? Solve by interpolation.

9. Solve Exercise 1 with the interest converted quarterly.

10. Solve Exercise 1 with the interest converted monthly.

11. Set up the series for the amount of an annuity of R at the end of each year for n years with interest at the nominal rate (j, m). Sum this series by (9) Art. 60, *Alg.: Com.—Stat.*, and thus obtain (8), Art. 24.

25. Present value of an annuity.—*The present value of an annuity is commonly defined as the sum of the present values of all the future payments.* Suppose an individual is to receive R dollars each year as an ordinary annuity and the payments are to last for n years. The individual may

do any one of three things with this annuity: (a) He may spend the payments as they are received; (b) accumulate the payments until the end of the last rent period (n years); (c) or sell the future payments to a bank (or similar institution) at the beginning of the first rent period.

If the same rate of interest is used to accumulate the payments as is used by the bank (or similar institution) in finding the present value of the future payments, it is evident that the sum (present value) paid to the individual by the bank at the beginning of the first rent period is equivalent to the present value of the sum to which the future payments will accumulate by the end of the last rent period.   Consequently, we may also define the present value of an annuity as *that sum, which, placed at interest at a given rate at the beginning of the first rent period, will accumulate to the amount of the annuity by the end of the last rent period.   Thus, it is the discounted value of S.*

Example 1.   It is provided by contract that a young man receive $500 one year from now and a like sum each year thereafter until 5 such payments in all have been received.   Not wishing to wait to receive these payments as they come due, the young man sells the contract to a bank. If the bank desires to invest its funds at 6% interest compounded annually, how much does the young man receive now for his contract?

Solution.
The first payment is made one year from now and has a present value of $500(1.06)^{-1}$.

The second payment is due two years from now and has a present value of $500(1.06)^{-2}$, and so on until the last payment which has a present value of $500(1.06)^{-5}$.   Summing up, we have

$$\text{Present value} = \$500(1.06)^{-1} + \$500(1.06)^{-2} + \ldots + \$500(1.06)^{-5}. \quad (9)$$

We notice that (9) is a geometrical progression having $500(1.06)^{-1}$ for the first term, $(1.06)^{-1}$ for ratio, and 5 for the number of terms.   Substituting in (8), Art. 60, *Alg.: Com.—Stat.* we find

$$A = \text{Present value} = \frac{500(1.06)^{-1}[(1.06)^{-5} - 1]}{(1.06)^{-1} - 1}.$$

Multiplying the numerator and denominator of the above expression by (1.06),

$$A = \text{Present value} = \frac{500[(1.06)^{-5} - 1]}{1 - (1.06)}$$

$$A = 500\,\frac{1 - (1.06)^{-5}}{0.06}$$

$$A = 500(4.21236379) \qquad [\text{Table VI}]$$

$$A = \$2,106.182.$$

If the young man had waited to receive the payments as they became due and immediately invested them at 6% converted annually, his investments at the end of 5 years would have amounted to

$$S = 500\,\frac{(1.06)^5 - 1}{0.06} = \$2,818.546.$$

We notice that \$2,818.546 is the amount of \$2,106.182 for 5 years at 6%. For

$$\$2,106.182(1.06)^5 = 2,106.182(1.33822558) = \$2,818.546.$$

We shall now find the present value of an annuity of \$1 per annum for n years at the effective rate i. The symbol $a_{\overline{n}|i}$ or $a_{\overline{n}|}$ is used to represent the present value of this annuity. To find this value, we shall discount each payment to the beginning of the term.
The first payment of 1 made at the end of the first year when discounted to the present, by Art. 17, has the present value of $(1 + i)^{-1}$. Similarly, the second payment when discounted to the present has a present value of $(1 + i)^{-2}$. And so on for the other payments. We then have

$$a_{\overline{n}|i} = (1 + i)^{-1} + (1 + i)^{-2} + (1 + i)^{-3} + \cdots + (1 + i)^{-n} \quad (10)$$

This is a geometric progression in which $a = (1 + i)^{-1}$, $r = (1 + i)^{-1}$, $l = (1 + i)^{-n}$. Finding the sum ($Alg.: Com.—Stat.$, Art. 60), we obtain

$$a_{\overline{n}|i} = \frac{1 - (1 + i)^{-n}}{i}. \tag{11}$$

The functions $a_{\overline{n}|i}$ and $s_{\overline{n}|i}$ are the two most important annuity functions. We frequently write them $a_{\overline{n}|}$ and $s_{\overline{n}|}$.

Formula (11) may be easily derived from (5) Art. 24. For $a_{\overline{n}|i}$ is, by definition, the discounted value of $s_{\overline{n}|i}$. That is,

$$a_{\overline{n}|i} = s_{\overline{n}|i} \cdot (1+i)^{-n} = \frac{(1+i)^n - 1}{i} \cdot (1+i)^{-n} = \frac{1 - (1+i)^{-n}}{i}.$$

If the annual rent is R, payable at the end of each year for n years, and if A represents the present value,

$$A = R \cdot a_{\overline{n}|i} = R \frac{1 - (1+i)^{-n}}{i}. \tag{12}$$

If the interest is at the nominal rate (j, m), using the relation (4) Art. 16,

$$1 + i = (1 + j/m)^m,$$

we find

$$A = R \frac{1 - \left(1 + \dfrac{j}{m}\right)^{-mn}}{\left(1 + \dfrac{j}{m}\right)^m - 1}, \tag{13}$$

which is easily reduced to

$$A = R \cdot a_{\overline{mn}|\frac{j}{m}} \cdot \frac{1}{s_{\overline{m}|\frac{j}{m}}}. \tag{13a}$$

26. Relation between $\dfrac{1}{a_{\overline{n}|}}$ and $\dfrac{1}{s_{\overline{n}|}}$.

We have $\qquad a_{\overline{n}|}(1+i)^n = s_{\overline{n}|}$ [Art. 25]

and $\qquad (1+i)^n = \dfrac{s_{\overline{n}|}}{a_{\overline{n}|}}.$

Substituting for $(1+i)^n$ in the equation

$$\frac{(1+i)^n - 1}{i} = s_{\overline{n}|}, \text{ we have}$$

$$\frac{s_{\overline{n}|} - a_{\overline{n}|}}{i a_{\overline{n}|}} = s_{\overline{n}|}.$$

Multiplying through by i and dividing through by $s_{\overline{n}|}$, we find

$$\frac{1}{a_{\overline{n}|}} - \frac{1}{s_{\overline{n}|}} = i,$$

or

$$\frac{1}{s_{\overline{n}|}} = \frac{1}{a_{\overline{n}|}} - i. \tag{14}$$

Table VII gives values for $\dfrac{1}{a_{\overline{n}|}}$. According to (14), values for $\dfrac{1}{s_{\overline{n}|}}$ are obtained by subtracting the rate i from the table values of $\dfrac{1}{a_{\overline{n}|}}$. Thus, to find $1/s_{\overline{20}|.04}$, we look up Table VII and obtain $1/a_{\overline{20}|.04} = 0.0735\,8175$ Using relation (14), we find

$$\frac{1}{s_{\overline{20}|.04}} = 0.0735\,8175 - .04 = 0.0335\,8175.$$

27. Summary. Formulas of an ordinary annuity of annual rent R payable annually for n years.

I. Interest at effective rate i.

$$1. \quad S = R\,\frac{(1+i)^n - 1}{i} = R.\ s_{\overline{n}|i}.$$

$$2. \quad A = R\,\frac{1 - (1+i)^{-n}}{i} = R.\ a_{\overline{n}|i}.$$

II. Interest at nominal rate (j, m).

$$1. \quad S = R\,\frac{\left(1+\dfrac{j}{m}\right)^{mn} - 1}{\left(1+\dfrac{j}{m}\right)^{m} - 1} = R.\,s_{\overline{mn}|\frac{j}{m}} \cdot \frac{1}{s_{\overline{m}|\frac{j}{m}}}$$

$$2. \quad A = R\,\frac{1 - \left(1+\dfrac{j}{m}\right)^{-mn}}{\left(1+\dfrac{j}{m}\right)^{m} - 1} = R.\ a_{\overline{mn}|\frac{j}{m}} \cdot \frac{1}{s_{\overline{m}|\frac{j}{m}}}$$

where

$$s_{\overline{n}|i} = \frac{(1+i)^n - 1}{i}, \qquad a_{\overline{n}|i} = \frac{1 - (1+i)^{-n}}{i},$$

$$s_{\overline{n}|i} = (1+i)^n \cdot a_{\overline{n}|i}, \qquad a_{\overline{n}|i} = (1+i)^{-n} \cdot s_{\overline{n}|i},$$

$$\frac{1}{a_{\overline{n}|i}} - \frac{1}{s_{\overline{n}|i}} = i.$$

28. Other derivations of $a_{\overline{n}|}$ and $s_{\overline{n}|}$.—We have derived the formulas for $a_{\overline{n}|}$ and $s_{\overline{n}|}$ by setting up series and then finding their sums by the formula for summing a geometric progression. It is of great value to derive the

formulas by a method called "direct reasoning" by some authorities, or "verbal interpretation" by other authorities.

Consider \$1 at 0. Its value at the end of n years is $(1 + i)^n$.
Also, from another point of view, \$1 at 0 will produce an annuity of i at the end of each year for n years and leave the original principal intact at the end of n years. For, at the end of the first year the amount is $(1 + i)$. Deposit the i into a separate account, and let the original principal \$1 again earn interest. It amounts to $(1 + i)$ at the end of the second year. We again deposit the i in the second account, and let the principal \$1 again earn interest. We continue this for n years. We thus find that \$1 at 0 is equivalent to an annuity of i for n years plus the original principal \$1 at n. In other words,

1 at 0 = [an annuity of i for n years] + 1 at n.
Let us now focalize all sums at the end of n years. Then

$$(1 + i)^n = i\, s_{\overline{n}|} + 1,$$

or, solving for $s_{\overline{n}|}$,

$$s_{\overline{n}|} = \frac{(1 + i)^n - 1}{i}.$$

If we focalize all sums at the present, 0, we have

$$1 = i\, a_{\overline{n}|} + (1 + i)^{-n},$$

or,

$$a_{\overline{n}|} = \frac{1 - (1 + i)^{-n}}{i}.$$

Exercises

1. An individual is to receive an inheritance of \$1,000 at the end of each year for 15 years. If money is worth 5% effective, what is the present value of the inheritance?

2. Find the present value of an ordinary annuity of \$1,000 a year for 12 years at $(j = .05,\ m = 2)$.

3. How much money, if deposited with a trust company paying $(j = .04,\ m = 2)$, is sufficient to pay a person \$2,000 a year for 20 years, the first payment to be received 1 year from the date of deposit?

4. An article is listed for $2,000 cash. A buyer wishes to purchase it in four equal annual installments, the first to be made 1 year from the date of purchase. If money is worth 6%, what is the amount of each installment?

5. A house was purchased for $12,000, of which $3,000 was cash. The balance was paid in 10 equal annual installments which began one year from the date of purchase. If money is worth $(j = .06, m = 2)$, find the amount of each installment.

6. A house is offered for sale on the following terms: $1,000 down, and $500 at the end of each year for 10 years. If money is worth 6%, what is a fair cash price?

7. Prove: $s_{\overline{1}|} + s_{\overline{2}|} + s_{\overline{3}|} + \cdots + s_{\overline{n}|} = \dfrac{(1+i)\, s_{\overline{n}|} - n}{i}$.

8. Prove: $\displaystyle\sum_{x=1}^{n} a_{\overline{x}|} = \dfrac{n - a_{\overline{n}|}}{i}$.

9. Prove: $\displaystyle\sum_{x=1}^{n} a_{\overline{2x}|} = \dfrac{1}{i}\left[n - \dfrac{a_{\overline{2n}|}}{s_{\overline{2}|}} \right]$.

10. Evidently $1 at 0 is equivalent to an annuity of $1/a_{\overline{n}|}$ at the end of each year for n years since the present value of the annuity is 1. Use this fact with Art. 28 to prove that

$$\frac{1}{a_{\overline{n}|}} = \frac{1}{s_{\overline{n}|}} + i.$$

11. Show that $a_{\overline{m+n}|} = a_{\overline{m}|} + (1+i)^{-m} a_{\overline{n}|} = a_{\overline{n}|} + (1+i)^{-n} a_{\overline{m}|}$.

    (a) by verbal interpretation. Draw line diagram.

    (b) algebraically.

12. Find the value of $a_{\overline{120}|.04}$ by using the relation in Exercise 11.

13. Show that $s_{\overline{m+n}|} = (1+i)^n s_{\overline{m}|} + s_{\overline{n}|} = (1+i)^m s_{\overline{n}|} + s_{\overline{m}|}$.

14. Find the value of $s_{\overline{120}|.04}$ by using the relation in Exercise 13.

15. What do the formulas in Exercises 11 and 13 become if $m = 1$?

B. Annuity Payable p Times a Year

29. Amount of an annuity, where the annual rent, R, is payable in p equal installments.—In Art. 15, we derived the value of the compound amount of $1 for n years, $(1+i)^n$, for integral values of n. We shall assume this relation to hold for fractional as well as for integral values of n. Consider

Example 1. $50 is deposited in a savings bank at the end of every six months for 4 years. If it accumulates at 5% interest, converted annually, what is the total amount on deposit at the end of 4 years?

Solution.
The first deposit of $50 is made at the end of six months and accumulates for $3\frac{1}{2}$ years. At the end of 4 years it will amount to $\$50(1.05)^{7/2}$.

The second deposit of $50 is made at the end of the first year and will amount to $\$50(1.05)^3$ at the end of 4 years.

The third deposit of $50 will amount to $\$50(1.05)^{5/2}$ at the end of 4 years, and so on.

Next to the last deposit will be at interest six months and will amount to $\$50(1.05)^{1/2}$ at the end of 4 years and the last deposit will be made at the end of 4 years and will draw no interest.

Hence, the total amount at the end of 4 years will be given by

$$\$50(1.05)^{7/2} + \$50(1.05)^3 + \ldots + \$50(1.05)^{1/2} + \$50;$$

or $\$50 + \$50(1.05)^{1/2} + \$50(1.05) + \ldots + \$50(1.05)^{7/2}$ (15)

We notice that (15) is a geometrical progression having 50 for first term, $(1.05)^{1/2}$ for ratio, and 8 for the number of terms.

Substituting in (8), Art. 60, *Alg.: Com.—Stat.*, we have

$$S = \text{Amount} = \frac{50[(1.05)^4 - 1]}{(1.05)^{1/2} - 1}.$$

Using Table III and Table VIII, we have

$$S = \text{Amount} = \frac{50(1.21550625 - 1)}{1.02469508 - 1}$$

$$S = \frac{50(0.21550625)}{0.02469508} = 436.34.$$

Hence, the amount of the above annuity is $436.34.

Let us now find the amount of an annuity of $1 per annum, payable in p equal installments of $1/p$ at the end of every pth part of a year for n years at rate i, converted annually.

To assist him in following this discussion the student should draw a line diagram.

The amount of an annuity of $1 per annum, payable in p equal installments at equal intervals during the year, will be denoted by the symbol, $s_{\overline{n}|}^{(p)}$. If the interest is converted annually, and i is the rate, $s_{\overline{n}|}^{(p)}$ can be expressed in terms of n, i, and p as follows: At the end of the first pth part of a year, $1/p$ is paid. This sum will remain at interest for $(n - 1/p)$ years and will amount to $1/p(1 + i)^{n-1/p}$.

The second installment of $1/p$ will be paid at the end of the second pth part of a year and will be at interest for $(n - 2/p)$ years, amounting to

$1/p(1 + i)^{n-2/p}$ at the end of n years, and so on until np installments are paid.

Next to the last installment will be at interest for one pth part of a year and will amount to $1/p(1 + i)^{1/p}$.

The last installment will be paid at the end of n years and will draw no interest. Adding all of these installments, beginning with the last one, we have

$$s_{\overline{n}|}^{(p)} = \frac{1}{p} + \frac{1}{p}(1 + i)^{1/p} + \frac{1}{p}(1 + i)^{2/p} + \ldots + \frac{1}{p}(1 + i)^{n-1/p}. \quad (16)$$

We notice that (16) is a geometrical progression having $1/p$ for first term, $(1 + i)^{1/p}$ for ratio, and np for the number of terms. Substituting in (8), Art. 60, *Alg.: Com.—Stat.*, we have

$$s_{\overline{n}|}^{(p)} = \frac{(1 + i)^n - 1}{p[(1 + i)^{1/p} - 1]}. \quad (17)$$

If the annual rent is R, we have

$$S = R\frac{(1 + i)^n - 1}{p[(1 + i)^{1/p} - 1]}. \quad (18)$$

For convenience in evaluating, (18) may be written, (4′) Art. 16,

$$S = R\frac{(1 + i)^n - 1}{i} \cdot \frac{i}{p[(1 + i)^{1/p} - 1]}, \quad (19)$$

or

$$S = R(s_{\overline{n}|})\left(\frac{i}{j_p}\right). \quad (19a)$$

Table X gives values of $\dfrac{i}{j_p}$.

Example 2. Find the amount of an annuity of $1,200 per year paid in quarterly installments of $300 for 7 years if the interest rate is 5% converted annually.

Solution. Here, $R = \$1,200$, $n = 7$, $p = 4$, and $i = 0.05$. Substituting in (19), we have

$$S = 1,200\frac{(1.05)^7 - 1}{0.05} \cdot \frac{0.05}{4[(1.05)^{1/4} - 1]} = 1200.s_{\overline{7}|}\left(\frac{.05}{j_4}\right).$$

Using Table V and Table X, we have

$$S = 1,200(8.14200845)(1.01855942) = 9,951.74.$$

Hence, the amount of the above annuity is $9,951.74.

Example 3. Find the amount of an annuity of \$200 per year paid in semi-annual installments for 10 years, the interest rate being 4.3% converted annually.

Solution. Here, $R = \$200$, $n = 10$, $p = 2$, and $i = 0.043$. The rate, 4.3%, is not given in our tables. We will evaluate by means of logarithms, using (18).

$$S = 200 \frac{(1.043)^{10} - 1}{2[(1.043)^{\frac{1}{2}} - 1]}.$$

$$\log 1.043 = 0.0182843 \qquad \text{(Table II.)}$$

$$10(\log 1.043) = 0.1828430$$

$$(1.043)^{10} = 1.5235 \qquad \text{(Table I.)}$$

$$\tfrac{1}{2}(\log 1.043) = 0.0091422$$

$$(1.043)^{\frac{1}{2}} = 1.021274 \qquad \text{(Table II.)}$$

Hence, $\quad S = \dfrac{200(1.5235 - 1)}{2(1.021274 - 1)} = \dfrac{100(0.5235)}{0.021274} = 2{,}460.75.$

Consequently, the amount of the above annuity is \$2,460.75, and it is accurate to five significant digits. That is, the exact value is between \$2,460.75 and \$2,460.65.

Exercises

Find the amount of the following annuities:

1. \$300 per year paid in semi-annual installments for 10 years at 4% interest converted annually.

2. \$500 per year paid in quarterly installments for 20 years at 5% converted annually.

3. \$50 per month for 10 years at 4% interest converted annually.

4. \$250 at the end of every six months for 15 years at 4½% converted annually. Evaluate by logarithms, using (18), and then check the result by using Tables V and X.

5. \$100 quarterly for 12 years at 3¼% converted annually.

6. A young man saves \$50 a month and deposits it each month in a savings bank for 25 years. If the bank pays 3½% interest, converted annually, how much does he have on deposit at the end of the 25 years?

7. Solve Exercise 1, if it were paid in quarterly installments. Is the answer more or less than the answer of Exercise 1? Explain the difference.

8. Solve Exercise 2, if it were paid in semi-annual installments. Is the answer more or less than the answer of Exercise 2? Explain the difference.

9. \$100 is deposited in a savings bank at the end of every 3 months. If it accumulates at 3% converted annually, how much is on deposit at the end of 4 years? Solve fundamentally as a geometrical progression.

Let us now find the amount of an annuity paid in p equal installments each year where the interest is converted more than once a year. We will illustrate by an example.

Example 4. $25 is deposited in a savings bank at the end of every three months for 4 years. If it accumulates at 5% interest, converted semi-annually, what is the total amount on deposit at the end of 4 years?

Solution. The first deposit of $25 is made at the end of three months and is at interest for $3\tfrac{3}{4}$ years. At the end of 4 years it will amount to

$$\$25(1.025)^{15/2}. \quad [(5), \text{ Art. 16.}]$$

The second deposit of $25 is made at the end of six months and is at interest for $3\tfrac{1}{2}$ years. At the end of 4 years it will amount to

$$\$25(1.025)^{7}.$$

The third deposit of $25 is made at the end of nine months and is at interest for $3\tfrac{1}{4}$ years. At the end of 4 years it will amount to

$$\$25(1.025)^{13/2}, \text{ and so on.}$$

Next to the last deposit of $25 will be at interest for $\tfrac{1}{4}$ year and will amount to

$$\$25(1.025)^{1/2}.$$

The last deposit of $25 is made at the end of 4 years and draws no interest.

Hence, the total amount on deposit at the end of 4 years will be given by

$$\$25(1.025)^{15/2} + \$25(1.025)^{7} + \cdots + \$25(1.025)^{1/2} + \$25$$

or $\quad \$25 + \$25(1.025)^{1/2} + \$25(1.025) + \ldots + \$25(1.025)^{15/2}. \quad (20)$

We notice that (20) is a geometrical progression having 25 for first term, $(1.025)^{1/2}$ for ratio, and 16 for the number of terms. Substituting in (8), Art. 60, *Alg.: Com.—Stat.*, we have

$$S = \text{Amount} = \frac{25\{[(1.025)^{1/2}]^{16} - 1\}}{(1.025)^{1/2} - 1}$$

$$S = \frac{25[(1.025)^{8} - 1]}{(1.025)^{1/2} - 1}. \quad (21)$$

Using Table III and Table VIII, we have

$$S = \text{Amount} = \frac{25(1.21840290 - 1)}{1.01242284 - 1}$$

$$S = \frac{25(0.21840290)}{0.01242284} = 439.50.$$

Hence, the amount of the above annuity is \$439.50.

If the interest is converted m times per year, we may substitute $\left(1 + \dfrac{j}{m}\right)^m$ for $(1 + i)$ in (18) and obtain

$$S = R \frac{\left(1 + \dfrac{j}{m}\right)^{mn} - 1}{p\left[\left(1 + \dfrac{j}{m}\right)^{m/p} - 1\right]}. \tag{22}$$

Let us consider further equation (21). Here $p = 4$, $m = 2$, and hence p/m is an integer. We may write (21) in the form

$$S = \frac{100}{2} \cdot \frac{[(1.025)^8 - 1]}{.025} \cdot \frac{.025}{2[(1.025)^{\frac{1}{2}} - 1]}. \tag{21a}$$

$$= 50.s_{\overline{8}|} \cdot \frac{.025}{j_2}.$$

When $\dfrac{p}{m}$ is an integer, (22) becomes

$$S = \frac{R}{m} \cdot s_{\overline{mn}|\frac{j}{m}} \cdot \frac{\dfrac{j}{m}}{j_{\frac{p}{m}} \text{ at rate } \dfrac{j}{m}}. \tag{22a}$$

When p/m is an integer, (22) can easily be reduced to (22a) in which case we may apply Tables V and X. This transformation simplifies the arithmetical computation since S is expressed as a continued product.

Example 5. Find the amount of an annuity of \$600 per year paid in quarterly installments for 8 years, if the interest rate is 5% converted semi-annually.

Solution. Here, $R = \$600$, $n = 8$, $p = 4$, $m = 2$, and $j = 0.05$. Substituting in (22), we have

$$S = 600 \frac{(1.025)^{16} - 1}{4[(1.025)^{\frac{3}{4}} - 1]}$$

$$= 300 \frac{(1.025)^{16} - 1}{2[(1.025)^{\frac{1}{2}} - 1]}$$

$$= 300 \frac{(1.025)^{16} - 1}{0.025} \cdot \frac{0.025}{2[(1.025)^{\frac{1}{2}} - 1]} = 300 \cdot s_{\overline{16}|} \cdot \frac{.025}{j_2}.$$

Using Table V and Table X, we find

$$S = 300(19.38022483)(1.00621142) = \$5,850.18.$$

Example 6. Solve Example 5, if the interest is converted quarterly.

Solution. Here, $R = \$600$, $n = 8$, $m = p = 4$, and $j = 0.05$. Substituting directly in (22),

$$S = 150 \frac{(1.0125)^{32} - 1}{0.0125} = 150\, s_{\overline{32}|.0125}$$

$$= 150(39.05044069) \quad \text{(Table V)}$$

$$= \$5,857.57.$$

Example 7. Solve Example 5, if the payments are made semi-annually and the interest is converted quarterly.

Solution. Here, $R = \$600$, $n = 8$, $p = 2$, $m = 4$, and $j = 0.05$. Substituting in (22), we have

$$S = 600 \frac{(1.0125)^{32} - 1}{2[(1.0125)^{\frac{4}{2}} - 1]}$$

$$= 300 \frac{(1.0125)^{32} - 1}{(1.0125)^2 - 1}$$

$$= \frac{300(1.48813051 - 1)}{1.02515625 - 1} \quad \text{(Table III)}$$

$$= \frac{300(0.48813051)}{0.02515625} = \$5,821.18.$$

In this example, m/p is an integer. When this is true we can write S as a product. Thus,

$$S = \frac{600}{2} \cdot \frac{(1.0125)^{32} - 1}{.0125} \cdot \frac{.0125}{(1.0125)^2 - 1} = 300 \cdot s_{\overline{32}|} \cdot \frac{1}{s_{\overline{2}|}}$$

in which Tables V and VII may be applied. In terms of annuity symbols, it is of the form

$$S = \frac{R}{p} \cdot s_{\overline{mn}|\frac{j}{m}} \cdot \frac{1}{s_{\overline{\frac{m}{p}}|\frac{j}{m}}} \cdot \tag{22b}$$

When m/p is an integer, (22) can easily be reduced to (22b).

Formula (22) is our most general formula for finding the amount of an annuity. The other forms (5), (8), and (18) are special cases of (22). Thus,

If $m = p = 1$, (22) reduces to

$$S = R\frac{(1 + i)^n - 1}{i}. \tag{5}$$

If $p = 1$ and $m > 1$, (22) reduces to

$$S = R\frac{\left(1 + \dfrac{j}{m}\right)^{mn} - 1}{\left(1 + \dfrac{j}{m}\right)^{m} - 1}. \tag{8}$$

If $m = 1$ and $p > 1$, (22) reduces to

$$S = R\frac{(1 + i)^n - 1}{p[(1 + i)^{1/p} - 1]}. \tag{18}$$

If $m = p$, (22) reduces to

$$S = \frac{R}{p}\frac{\left(1 + \dfrac{j}{p}\right)^{np} - 1}{\dfrac{j}{p}}. \tag{23}$$

We observe that (23) is of the same form as (5), where n is replaced by np, i by j/p, and R by R/p.

In solving annuity problems the student should confine himself to the use of the fundamental formulas. Thus, if his problem requires that he find the amount of an annuity, he should use (5), (8), (18), or (22), and then effect the necessary transformation to reduce it to the annuity symbols that will entail the least amount of labor in obtaining the numerical result.

Exercises

1. A man deposits $150 in a 4% savings bank at the end of every three months. If the interest is converted semi-annually, what amount will be to his credit at the end of 10 years?

2. Solve Exercise 1, with the interest converted (a) annually, (b) quarterly.

3. A man wishes to provide a fund for his retirement and begins at age 25 to deposit $125 at the end of every three months with a trust company which allows 3% interest converted semi-annually. What will be the amount of the fund at age 60?

4. Solve Exercise 3, with the interest converted quarterly.

5. Fill out the following table for the amount of an annuity of $300 per year for 12 years at 4%:

Annuity Payable	Interest Convertible		
	Annually	Semi-annually	Quarterly
Annually			
Semi-annually			
Quarterly			

6. Solve Exercise 5, with the rate of interest 5%.

7. Solve Exercise 5, with the rate of interest $4\frac{1}{2}$ %.

8. Find the amount of an annuity of $400 a year for 7 years at 7% interest converted semi-annually. Solve fundamentally as a geometrical progression using the principle of compound interest.

9. Solve Exercise 8, with the interest converted annually.

10. Solve Exercise 8, with the annuity payable in quarterly installments and the interest converted semi-annually.

11. $250 is deposited at the end of every six months for 10 years in a fund paying 4% converted semi-annually. Then, $150 is deposited at the end of every three months for 10 years and the interest rate is reduced to 3% converted quarterly. Find the total amount on deposit at the end of 20 years.

12. A man has $2,500 invested in Government bonds which will mature in 15 years. These bonds bear 3% interest, payable January 1 and July 1. When these interest payments are received they are immediately deposited in a savings bank which allows $3\frac{1}{2}$% interest converted semi-annually. To what amount will these interest payments accumulate by the end of 15 years?

13. A man begins at the age of thirty to save $15 per month, and keeps all of his savings invested at an average rate of 4% effective. How much will he have as a retirement fund when he is sixty-five years old?

14. A man 25 years of age pays $41.85 at the beginning of each year for 20 years for which he receives an insurance contract which will pay his estate $1,000 in case of his death before 20 years and pay him $1,000 cash, if living, at the end of 20 years. He also decides to deposit the same amount at the beginning of each year in a savings bank paying 3% interest. Compare the value of the two investments at the end of 20 years. On the basis of 3% interest what would you say his insurance protection cost for the 20 years?

15. A man deposits $150 in a savings bank on his twenty-fifth birthday and a like amount every six months. If the bank pays 3% interest convertible semi-annually, how much does he have on deposit on his sixtieth birthday?

16. Solve Exercise 15, with the interest converted quarterly.

17. A man, age 25, pays $24.03 a year in advance on a $1,000, 20-payment life policy. If he should die at the end of 12 years, just before paying the 13th premium, how much

would his estate be increased by having taken the insurance instead of having deposited the \$24.03 each year in a savings bank paying 4% effective?

18. Find the amount of an annuity of \$200 a year payable in semi-annual installments for 7 years at 4% converted annually. Solve fundamentally as a geometrical progression.

19. Solve Exercise 18, with the interest converted quarterly.

20. Assume that R/p dollars is invested at the end of $1/p$th of a year, at nominal rate j converted m times a year, and that a like amount is invested every pth part of a year until np such investments are made; sum up as a geometrical progression and thereby derive the formula (22).

30. Present value of an annuity of annual rent, R, payable in p equal installments.—In Art. 25 we considered the problem of finding the present value of an ordinary annuity with annual payments. We are now ready to consider the problem of finding the present value of an ordinary annuity of annual rent, R, with p payments a year.

$$\begin{array}{ccccccc} A & & & & & & S \\ \vdash & & & & & & \dashv \\ 0 & 1 & 2 & 3 & \cdots & n-1 & n \end{array}$$
We have found the amount S of such an annuity. When the interest is at the effective rate i, the amount S is given by (18); when the interest is at the nominal rate (j, m), the amount S is given by (22). If, as usual, A designates the present value of the annuity, evidently

$$A(1+i)^n = S = R\frac{(1+i)^n - 1}{p[(1+i)^{1/p} - 1]} \tag{24}$$

if the interest is at the effective rate i, and

$$A\left(1+\frac{j}{m}\right)^{mn} = S = R\cdot\frac{\left(1+\dfrac{j}{m}\right)^{mn} - 1}{p\left[\left(1+\dfrac{j}{m}\right)^{m/p} - 1\right]} \tag{25}$$

if the interest is at the nominal rate (j, m).

Solving (24) and (25) respectively for A, we obtain

$$A = R\frac{1 - (1+i)^{-n}}{p[(1+i)^{1/p} - 1]}, \tag{26}$$

and

$$A = R\frac{1 - \left(1+\dfrac{j}{m}\right)^{-mn}}{p\left[\left(1+\dfrac{j}{m}\right)^{m/p} - 1\right]}. \tag{27}$$

We shall leave it as an exercise for the reader to show that (26) can be reduced to the form

$$A = R \cdot a_{\overline{n}|i} \cdot \frac{i}{j_p}.$$

and that (27) can be reduced to the forms

$$A = \frac{R}{m} \cdot a_{\overline{mn}|\frac{j}{m}} \cdot \frac{\frac{j}{m}}{j_{\frac{p}{m}} \text{ at rate } \frac{j}{m}}, \quad \frac{p}{m} \text{ an integer,} \tag{28a}$$

$$A = \frac{R}{p} \cdot a_{\overline{mn}|\frac{j}{m}} \cdot \frac{1}{s_{\overline{\frac{m}{p}}|\frac{j}{m}}}, \quad \frac{m}{p} \text{ an integer.} \tag{28b}$$

It is of great value to derive the fundamental formulas (26) and (27) by discounting each payment R/p to the present and finding the sum of the respective series. See p. 59. We shall set up the series and leave the details of summation and simplification to the reader.

If the interest is at the effective rate i, the present value is

$$A = \frac{R}{p} \left[(1+i)^{-1/p} + (1+i)^{-2/p} + \ldots + (1+i)^{-n} \right],$$

which simplifies to the value given in (26).

If the interest is at the nominal rate (j, m), the present value is

$$A = \frac{R}{p} \left[\left(1 + \frac{j}{m}\right)^{-m/p} + \left(1 + \frac{j}{m}\right)^{-2m/p} + \ldots + \left(1 + \frac{j}{m}\right)^{-mn} \right],$$

which simplifies to the value given in (27).

Again we would advise the student, when solving annuity problems, to confine himself to the fundamental formulas. Thus, if his problem requires that he find the present value of an annuity, he should use (12), (13), (26), or (27), and then effect the necessary transformation to reduce it to the annuity symbols that will entail the least amount of labor in obtaining the numerical result.

31. Summary of ordinary annuity formulas.

$$S = \text{The Amount of the Annuity.}$$

$$A = \text{The Present Value of the Annuity.}$$

A. Annuity of annual rent R payable annually for n years.

     I. At the effective rate i.

         1. $S = R \dfrac{(1 + i)^n - 1}{i} = R \cdot s_{\overline{n}|}$ (5)

         2. $A = R \dfrac{1 - (1 + i)^{-n}}{i} = R \cdot a_{\overline{n}|}$ (12)

     II. At the nominal rate (j, m).

         1. $S = R \dfrac{\left(1 + \dfrac{j}{m}\right)^{mn} - 1}{\left(1 + \dfrac{j}{m}\right)^{m} - 1} \cdot$ (8)

         2. $A = R \dfrac{1 - \left(1 + \dfrac{j}{m}\right)^{-mn}}{\left(1 + \dfrac{j}{m}\right)^{m} - 1} \cdot$ (13)

B. Annuity of annual rent R payable p times a year for n years.

     I. At the effective rate i.

         1. $S = R \dfrac{(1 + i)^n - 1}{p[(1 + i)^{1/p} - 1]} \cdot$ (18)

         2. $A = R \dfrac{1 - (1 + i)^{-n}}{p[(1 + i)^{1/p} - 1]} \cdot$ (26)

     II. At the nominal rate (j, m).

         1. $S = R \dfrac{\left(1 + \dfrac{j}{m}\right)^{mn} - 1}{p\left[\left(1 + \dfrac{j}{m}\right)^{m/p} - 1\right]} \cdot$ (22)

         2. $A = R \dfrac{1 - \left(1 + \dfrac{j}{m}\right)^{-mn}}{p\left[\left(1 + \dfrac{j}{m}\right)^{m/p} - 1\right]} \cdot$ (27)

Example 1. Find the present value of an annuity of $600 per year paid in quarterly installments for 8 years, if the interest rate is 5% converted semi-annually.

Solution. Here, $R = \$600$, $n = 8$, $p = 4$, $m = 2$, and $j = 0.05$. Substituting in (27), we have

$$A = 600 \frac{1 - (1.025)^{-16}}{4[(1.025)^{3/4} - 1]} = 300 \frac{1 - (1.025)^{-16}}{2[(1.025)^{1/2} - 1]}$$

$$= 300 \frac{1 - (1.025)^{-16}}{0.025} \cdot \frac{0.025}{2[(1.025)^{1/2} - 1]}$$

$$= 300 \cdot a_{\overline{16}|.025} \cdot \frac{.025}{j_2 \text{ at } .025}$$

$$= 300(13.05500266)(1.00621142) \quad \text{[Tables VI and X]}$$

$$= \$3,940.83.$$

Example 2. Solve Example 1, with the interest converted quarterly.

Solution. Here, $R = \$600$, $n = 8$, $m = p = 4$, and $j = 0.05$. Substituting in (27),

$$A = 150 \frac{1 - (1.0125)^{-32}}{0.0125} = 150 \cdot a_{\overline{32}|.0125}$$

$$= 150(26.24127418) \quad \text{[Table VI]}$$

$$= \$3,936.19.$$

Example 3. Solve Example 1, if the payments are made semi-annually and the interest is converted quarterly.

Solution. Here, $R = \$600$, $n = 8$, $p = 2$, $m = 4$, and $j = 0.05$. Substituting in (27), we have

$$A = 600 \frac{1 - (1.0125)^{-32}}{2[(1.0125)^{1/2} - 1]}$$

$$= 300 \frac{1 - (1.0125)^{-32}}{(1.0125)^2 - 1}$$

$$= \frac{300(1 - 0.67198407)}{1.02515625 - 1} \quad \text{[Tables III and IV]}$$

$$= \frac{300(0.32801593)}{0.02515625} = \$3,911.74.$$

We may also solve this example by writing A in the form

$$A = 300 \frac{1 - (1.0125)^{-32}}{.0125} \cdot \frac{.0125}{(1.0125)^2 - 1}$$

and applying Tables VI and VII. We find

$$A = 300(26.2412\ 7418)\ (0.4968\ 9441)$$
$$= \$3911.74.$$

Exercises

1. Find the present value of an annuity of $700 per year running for 15 years at 5% converted annually.

2. Solve Exercise 1, assuming that the interest is converted semi-annually.

3. A piece of property is purchased by paying $1,000 cash and $500 at the end of each year for 10 years without interest. What would be the equivalent price if it were all paid in cash at the date of purchase, assuming money is worth $5\frac{1}{2}\%$?

4. In order that his daughter may receive an income of $800 payable at the end of each year for 5 years, a man buys such an annuity from an investment company. If the investment company allows 4% interest, converted annually, what sum does the man pay the company?

5. Solve Exercise 4, if the daughter is to receive $400 at the end of each six months.

6. The beneficiary of a policy of insurance is offered a cash payment of $10,000 or an annuity of $750 for 20 years, the first payment to be made one year hence. Allowing interest at $3\frac{1}{2}\%$ converted annually, which is the better option?

7. A building is leased for a term of 10 years at an annual rental of $1,200 payable annually at the end of the year. Assuming an interest rate of 5.2% what cash payment would care for the lease for the entire term of 10 years?

8. Show that the results of Examples 5, 6, and 7 of Art. 29 are the compound amounts of the results of Examples 1, 2, and 3 respectively of Art. 31.

9. An individual made a contract with an insurance company to pay his family an annual income of $4,000, payable in quarterly installments at the end of each quarter for 25 years. He paid for the contract in full at the time of purchase. Assuming money worth 4%, what did it cost?

10. Find the cost of the above annuity, with the interest converted quarterly.

11. Fill out the following table for the present value of an annuity of $100 per year for 10 years, interest at 4%.

Annuity Payable	Interest Convertible		
	Annually	Semi-annually	Quarterly
Annually			
Semi-annually			
Quarterly			

12. Solve Exercise 11, with the rate 5%.

13. Derive formulas (22) and (27) from (18) and (26) respectively by using the relation $(1 + i) = (1 + j/m)^m$.

14. How much money, if deposited with a trust company paying $(j = .04, m = 2)$, would be sufficient to provide a man with an income of $100 a month for 25 years?

15. A house is sold "like paying rent" for $50 a month for 12 years. What is the cash equivalent if money is worth 6%?

16. A coal mine is estimated to yield $10,000 a year for the next 12 years. The mine is for sale. What is the present value of the total yield of the mine on a 5% basis?

17. State problems for which the following would give the answers:

$$\text{(a)} \quad S = 600.\, s_{\overline{48}|.015} \cdot \frac{1}{s_{\overline{6}|.015}}.$$

$$\text{(b)} \quad A = 200.\, a_{\overline{25}|.025} \cdot \frac{.025}{j_2 \text{ at } .025}.$$

18. A widow is to receive from a life insurance policy $50 a month for 20 years. If money is worth 3%, what is a fair cash settlement?

19. A building and loan association accumulates its deposits at $(j = .06, m = 2)$. If a man makes monthly deposits of $35 each for 10 years, what sum should he have to his credit at the end of this time?

20. A man is offered a piece of property for $10,000. He wishes to make a cash payment and semi-annual payments of $500 for 10 years. What should be the cash payment if the seller discounts future payments at $(j = .06, m = 2)$?

32. Annuities due.—In the previous sections of this chapter, we have been concerned with ordinary annuities,—that is, annuities in which the payments were made at the *ends* of the payment periods. An **annuity due** is one in which the payments are made at the *beginnings* of the payment periods.

The **term** of an annuity due extends from the beginning of the first payment period to the end of the last payment period. That is, it extends for one payment period after the last payment has been made. The **amount** of the annuity due is the value of the annuity at the end of the last payment period, that is, at the end of the term. The **present value** of an annuity due is the value of the annuity at the beginning of the term, or at the time of the initial payment. The present value includes the initial payment.

To solve problems involving annuities due it is neither necessary nor desirable that we invent a number of new formulas*. We can always analyze an annuity due problem in terms of ordinary annuities. It is important, however, that the student have a clear picture of the problem.

---

* The symbols, $\mathbf{s}_{\overline{n}|}$ and $\mathbf{a}_{\overline{n}|}$, in black roman type are frequently used to represent the amount and the present value of an annuity due of 1 per year for n years.

We submit the following line diagrams to assist the student in clearly understanding the similarities and the differences between ordinary annuities and annuities due.
Example 1. $50 is deposited in a savings bank now and a like amount every six months until 8 such deposits in all have been made. How much is on deposit 4 years from now, if money accumulates at 5% converted annually?

Solution. Consider the line diagram.
First method. The amount of the annuity, S, just after the last deposit (at 3½ years) is that of an *ordinary* annuity with $R = 100$, $n = 4$, $p = 2$, $i = .05$. Using $BI1$, Art. **31**, we find this amount to be

$$S = \frac{100\left[(1.05)^4 - 1\right]}{2\ \left[(1.05)^{\frac{1}{2}} - 1\right]}$$

$$= 100 \cdot s_{\overline{4}|.05} \cdot \frac{.05}{j_2 \text{ at } .05}$$

$$= 100(4.3101\ 2500)(1.0123\ 4754)$$

$$= 436.3344.$$

Now evidently S' is the value of S accumulated for ½ a year. Hence

$$S' = S(1.05)^{\frac{1}{2}} = 436.3344(1.0246\ 9508)$$

$$= \$447.11.$$

Second method. If a deposit of \$50 had been made at the end of 4 years, the amount would have been that of an *ordinary* annuity with $R = 100$, $n = 4\frac{1}{2}$, $p = 2$, $i = .05$. Again using $BI1$, Art. 31, we find this amount to be

$$S'' = 50 \cdot \frac{(1.05)^{9\!/\!2} - 1}{(1.05)^{\frac{1}{2}} - 1}.$$

It is clear that the amount just before such a deposit was made, which is the amount S' that we are seeking, is

$$S' = S'' - 50 = 50 \cdot \frac{(1.05)^{9\!/\!2} - 1}{(1.05)^{\frac{1}{2}} - 1} - 50$$

$$= (1.05)^{\frac{1}{2}} \cdot \frac{50[(1.05)^4 - 1]}{(1.05)^{\frac{1}{2}} - 1} = (1.05)^{\frac{1}{2}} \cdot 100 \cdot s_{\overline{4|}} \cdot \frac{.05}{j_2}$$

$$= \$447.11.$$

Example 2. Find the amount of an annuity due of annual rent \$400 payable in quarterly installments for 8 years at 6% converted annually.

We shall leave it as an exercise for the student to show that the first method leads to the solution

$$S' = 400(1.06)^{\frac{1}{4}} \frac{(1.06)^8 - 1}{4[(1.06)^{\frac{1}{4}} - 1]}$$

$$= 400(1.06)^{\frac{1}{4}} \frac{(1.06)^8 - 1}{0.06} \cdot \frac{0.06}{4[(1.06)^{\frac{1}{4}} - 1]}$$

$$= 400(1.01467385)(9.89746791)(1.02222688)$$

$$\text{[Tables VIII, V, X]}$$

$$= \$4,106.36.$$

Example 3. Solve Example 2 with the interest converted quarterly.

We shall leave it as an exercise for the student to show that the second method leads to the solution

$$S' = 100\left[\frac{(1.015)^{33} - 1}{0.015} - 1 \right] = 100\left[s_{\overline{33|}.015} - 1 \right]$$

$$= 100(42.29861233 - 1) \quad \text{[Table V]}$$

$$= \$4,129.86.$$

Example 4. Solve Example 2 with the interest converted semi-annually. The application of the first method leads to the solution

$$S' = 400(1.03)^{\frac{1}{2}} \frac{(1.03)^{16} - 1}{4[(1.03)^{\frac{1}{2}} - 1]}$$

$$= 200(1.03)^{\frac{1}{2}} \frac{(1.03)^{16} - 1}{0.03} \cdot \frac{0.03}{2[(1.03)^{\frac{1}{2}} - 1]}$$

$$= 200(1.01488916)(20.1568813)(1.00744458)$$

[Tables VIII, V, X]

$$= \$4,120.85.$$

Exercises

1. Set up a series for the accumulated values of the payments in Example 1 above, find the sum of the resulting geometric progression, and thus find S'.

2. Do the same for Example 3 above.

3. A man deposits $150 in a savings bank on his twenty-fifth birthday and a like amount every six months. If the bank pays 3% interest convertible semi-annually, how much does he have on deposit on his sixtieth birthday?

4. Solve Exercise 3, with the interest converted quarterly.

5. A man, age 25, pays $24.03 a year in advance on a $1,000, 20-pay life policy. If he should die at the end of 12 years, just before paying the 13th premium, how much would his estate be increased by having taken the insurance instead of having deposited the $24.03 each year in a savings bank paying 4% effective?

6. An insurance premium of $48 is payable at the beginning of each year for 20 years. If the insurance company accumulates these payments at 5% converted semi-annually, find the amount of the payments at the end of the 20th year.

7. Find the amount of an annuity due of $200 a year payable in semi-annual installments for 7 years at 4% converted annually. Solve fundamentally as a geometrical progression.

8. Solve Exercise 7, with the interest converted quarterly.

We have defined the present value of an annuity due to be the value of the annuity at the time of the initial payment. Consider the examples:

Example 1. An individual is to receive $50 cash and a like sum every six months until 8 such payments in all have been made. What is the cash value of the payments, if money is worth 5% converted annually?
Solution. We shall solve this example by two methods.

First method. The payments constitute an *ordinary* annuity whose term begins 6 months before the present and ends at 3½ years. Its term

is therefore 4 years. We have for this annuity $R = \$100$, $n = 4$, $p = 2$, $i = .05$. Using $BI2$, Art. 31, we find

$$A = 100 \frac{1 - (1.05)^{-4}}{2[(1.05)^{\frac{1}{2}} - 1]}$$

Evidently A', the required present value, is the value A accumulated $\frac{1}{2}$ year at 5%. Hence

$$A' = (1.05)^{\frac{1}{2}}(100) \left[\frac{1 - (1.05)^{-4}}{0.05} \right] \left[\frac{0.05}{2[(1.05)^{\frac{1}{2}} - 1]} \right]$$

$$= 100(1.02469508)\,(3.54595050)\,(1.01234754)$$

$$= \$367.84. \qquad \text{[Tables VI, VIII, and X]}$$

Second Method. If we disregard the first payment, the remaining 7 payments constitute an *ordinary* annuity whose term begins now. The value at 0 of this annuity is the present value of an ordinary annuity with $R = 100$, $n = 3\frac{1}{2}$, $p = 2$, $i = .05$. Using $BI2$, Art. 31, the value at 0 is

$$A'' = 50 \cdot \frac{1 - (1.05)^{-\frac{7}{2}}}{(1.05)^{\frac{1}{2}} - 1}.$$

Hence

$$A' = A'' + 50 = (1.05)^{\frac{1}{2}}(100) \left[\frac{1 - (1.05)^{-4}}{0.05} \right] \left[\frac{0.05}{2[(1.05)^{\frac{1}{2}} - 1]} \right]$$

$$= 100(1.02469508)\,(3.54595050)\,(1.01234754)$$

$$= \$367.84. \qquad \text{[Tables VI, VIII, and X]}$$

Example 2. Find the present value of an annuity due of \$600 per year paid in quarterly installments for 8 years, if the interest rate is 5% converted semi-annually.

We shall leave it an exercise for the reader to show that the first method leads to the solution

$$A' = 600(1.025)^{\frac{1}{2}} \frac{1 - (1.025)^{-16}}{4[(1.025)^{\frac{1}{2}} - 1]}$$

$$= 300(1.025)^{\frac{1}{2}} \frac{1 - (1.025)^{-16}}{2[(1.025)^{\frac{1}{2}} - 1]}$$

$$= 300(1.025)^{\frac{1}{2}} \frac{1 - (1.025)^{-16}}{0.025} \cdot \frac{0.025}{2[(1.025)^{\frac{1}{2}} - 1]}$$

$$= 300(1.01242284)\,(13.05500266)\,(1.00621142)$$

$$= \$3,989.78. \qquad \text{[Tables VI, VIII, and X]}$$

Example 3. Solve Example 2 with the interest converted quarterly.

We leave it an exercise for the reader to show that the second method leads to the solution

$$A' = 150 \left[1 + \frac{1 - (1.0125)^{-31}}{0.0125} \right] = 150[1 + a_{\overline{31}|.0125}]$$

$$= 150(1 + 25.56929010) \quad \text{[Table VI]}$$

$$= 150(26.56929010) = \$3,985.39.$$

Example 4. Find the present value of an annuity due of \$600 per year paid in semi-annual installments for 8 years if the interest rate is 5% convertible quarterly.

An application of the first method leads to the solution

$$A' = 300(1.0125)^2 \cdot \frac{1 - (1.0125)^{-32}}{(1.0125)^2 - 1}$$

$$= 300(1.0125)^2 \cdot a_{\overline{32}|} \cdot \frac{1}{s_{\overline{2}|}} \text{ at } .0125$$

$$= \$4,010.15. \quad \text{[Tables III, VI and VII]}$$

Exercises

1. Set up a series for the present value of the payments in Example 1 above, find the sum of the resulting series, and thus find A'.

2. Do the same for Example 3 above.

3. A man leases a building for 4 years at a rental of \$100 a month payable in advance. Find the equivalent cash payment, if money is worth 5%.

4. A man pays \$500 cash and \$500 annually thereafter until 10 payments have been made on a house. Assuming money worth 6% converted semi-annually, what is the equivalent cash price?

5. An insurance policy provides that at the death of the insured the beneficiary is to receive \$1,200 per year for 10 years, the first payment being made at once. Assuming that money is worth 3½%, what is the value of a policy that will provide such a settlement?

6. Allowing interest at 5%, converted quarterly, what is the present cash value of a rental of \$2,000 per year, payable quarterly in advance for a period of 15 years?

7. Solve Exercise 6, with the payments made semi-annually.

8. A man deposits \$30 at the beginning of each month in a bank which pays 3% interest converted semi-annually. He makes these deposits for 120 months. What amount does he have to his credit at the end of the time.

9. Prove that $a_{\overline{n}|} = 1 + a_{\overline{n-1}|}$.

10. Prove that $s_{\overline{n}|} = (1 + i)s_{\overline{n}|} = s_{\overline{n+1}|} - 1$.

33. Deferred annuities.—*A deferred annuity is one whose payments are to begin at the end of an assigned number of years or periods.* When we say that an annuity is *deferred m* payment periods, we mean that the annuity is "entered upon" at the end of m payment periods and that the first payment is made at the end of $(m + 1)$ payment periods. The m periods constitute the *period of deferment.*

The *amount* of a deferred annuity is the value of the annuity immediately after the last payment. The *present value* of a deferred annuity is the value of the annuity at the beginning of the period of deferment.

The following line diagram emphasizes the characteristics of a deferred annuity that continues t payment periods after being deferred m payment periods.
To solve problems involving deferred annuities, it is neither necessary nor desirable that we invent a number of new formulas.* Problems involving deferred annuities can always be analyzed in terms of ordinary annuities. We shall illustrate the methods of solution by a few examples.

Example 1. A young man is to receive \$500 at the end of 6 years and a like sum each year thereafter until he has received 10 payments in all. Assuming money worth 4% converted annually what is the present value of his future income?

We shall solve this problem by two methods.

Solution. First method. Consider the line diagram.
The value of the annuity at the end of 5 years is evidently

$$A = 500 \cdot \frac{1 - (1.04)^{-10}}{0.04} = 500 \cdot a_{\overline{10}|.04}.$$

* The symbols $m \mid s_{\overline{n}|}$ and $m \mid a_{\overline{n}|}$ are frequently used to represent the **amount** and the present value of an annuity of 1 per year for n years deferred m years.

The value at 0, which is the value we are seeking, is A discounted 5 years at 4%.   Hence,

$$A' = (1.04)^{-5} A$$

$$= (1.04)^{-5} \left[500 \, \frac{1 - (1.04)^{-10}}{0.04} \right] = (1.04)^{-5} \cdot 500 \cdot a_{\overline{10}|.04}$$

$$= 500(0.82192711)\,(8.11089578) \quad \text{[Tables IV and VI]}$$

$$= \$3,333.28.$$

Solution.   Second method.

Imagine \$500 paid at the end of each year for the first five years. These payments together with the 10 given payments constitute an ordinary annuity of \$500 a year for 15 years.   Its value at 0 is $500 \cdot a_{\overline{15}|.04}$. Now, if we subtract the value at 0 of the five imaginary payments, namely $500 \, a_{\overline{5}|.04}$, we have

$$A' = 500 \, a_{\overline{15}|.04} - 500 \, a_{\overline{5}|.04} = 500 \, [a_{\overline{15}|.04} - a_{\overline{5}|.04}]$$

$$= 500(11.1183\ 8743 - 4.4518\ 2233) \quad \text{[Table VI]}$$

$$= \$3,333.28.$$

The second method is much simpler from the standpoint of computation.   The student, however, should become skilled in the use of both methods.

Example 2.   Find the present value of an annuity of \$600 per year paid in quarterly installments for 8 years but deferred 5 years, assuming money worth 5% converted semi-annually.

Solution.   We leave it as an exercise for the reader to show that the first method leads to

$$A' = 600(1.025)^{-10} \, \frac{1 - (1.025)^{-16}}{4[(1.025)^{\frac{3}{4}} - 1]}$$

$$= 300(1.025)^{-10} \, \frac{1 - (1.025)^{-16}}{0.025} \cdot \frac{0.025}{2[(1.025)^{\frac{1}{4}} - 1]}$$

$$= 300(0.78119840)\,(13.05500266)\,(1.00621142)$$

$$\text{[Tables IV, VI and X]}$$

$$= \$3,078.57.$$

Example 3. Solve Example 2 with the interest converted quarterly.

Solution. We shall leave it as an exercise for the reader to show that the second method leads to

$$A' = 150 \left[\frac{1 - (1.0125)^{-52}}{0.0125} - \frac{1 - (1.0125)^{-20}}{0.0125} \right]$$

$$= 150 \left[a_{\overline{52}|.0125} - a_{\overline{20}|.0125} \right]$$

$$= 150(38.06773431 - 17.59931613) \quad \text{[Table VI]}$$

$$= 150(20.46841818) = \$3,070.26.$$

Example 4. Find the present value of an annuity of \$600 a year paid in semi-annual installments for 8 years but deferred 5 years, assuming money is worth $(j = .05, m = 4)$.

Solution. We leave it as an exercise for the reader to show that the first method leads to

$$A' = 600(1.0125)^{-20} \frac{1 - (1.0125)^{-32}}{2[(1.0125)^{\frac{1}{2}} - 1]}$$

$$= 300(1.0125)^{-20} \frac{1 - (1.0125)^{-32}}{(1.0125)^2 - 1}$$

$$= \frac{300(0.78000855)(1 - 0.67198407)}{1.02515625 - 1} \quad \text{[Tables III and IV]}$$

$$= \frac{300(0.78000855)(0.32801593)}{0.02515625} = \$3,051.19.$$

Remark **1.** It will be noted that we have given no examples that involve finding the *amount* of a deferred annuity. The amount of a deferred annuity is obviously the amount of an ordinary annuity to which we have already given much attention.

Remark **2.** The second method for evaluating the present value of a deferred annuity is preferable when $m = p$.

Exercises

1. If money is worth $(j = .04, m = 2)$, find the present value of an annuity of \$1,000 a year, the first payment being due at the end of 8 years and the last at the end of 17 years.

2. Find the present value of an annuity of \$1,000 per year, payable in semi-annual installments, for 9 years but deferred 5 years assuming money worth 4% converted semi-annually. Solve by two methods.

3. Solve Exercise 2, with the interest converted annually.

4. Find the present value of an annuity of $800 per annum paid in quarterly installments for 14 years, deferred 6 years, if money is worth 5% converted annually.

5. Solve Exercise 4, with the interest converted (a) semi-annually, (b) quarterly.

6. A will provides that a son, aged 15 years, is to receive $1,000 when he reaches 25 and a like sum each year until he has received 15 payments in all. Assuming money worth 4% converted annually, what would be the inheritance tax of 5% on the son's share?

7. A geologist estimates that an oil well will produce a net annual income of $50,000 for 10 years. Due to litigations the first income will not be available until the end of 4 years, but will come in at the end of each year thereafter until 10 full payments have been made. Assuming money worth 5½%, what is the present value of the well?

8. What sum should be set aside now to assure a person an income of $150 at the end of each month for 20 years, if the income is deferred for 12 years, assuming money worth 4½% converted semi-annually?

9. A man offers to sell his farm for $15,000 cash or $7,500 cash and $2,500 annually for 4 years, the first annual payment to be made at the end of 5 years. Assuming money worth 6%, what is the cash difference between the two offers?

10. What sum of money should a man set aside at the birth of his son in order to provide $1,000 a year for 4 years to take care of the son's education, if the first installment is to be paid in 18 years? Assume 4% interest.

11. Prove: $m \mid a_{\overline{n}|i} = (1 + i)^{-m} a_{\overline{n}|i}$.

12. Prove: $m \mid a_{\overline{n}|i} = a_{\overline{m+n}|i} - a_{\overline{m}|i}$.

34. Finding the interest rate of an annuity.—We may find the approximate interest rate of an annuity by the method of interpolation. This method will be sufficiently accurate for all practical purposes.

Example 1. At what rate, converted quarterly, will an annuity of $100 per quarter amount to $5,100 in 10 years?

Solution. Here, $R = \$400$, $m = p = 4$, $n = 10$, and $S = \$5,100$. Substituting in $BII1$, Art. 31, we have

$$5,100 = 100 \frac{\left(1 + \dfrac{j}{4}\right)^{40} - 1}{\dfrac{j}{4}} = 100 s_{\overline{40}|\frac{j}{4}}.$$

Then $s_{\overline{40}|\frac{j}{4}} = 51.0000$. We now turn to Table V and follow $n = 40$ until we come to a value just less than 51.0000 and one just greater than 51.0000. We find the value 50.1668 corresponding to 1⅛% and the

value 51.4896 corresponding to $1\tfrac{1}{4}\%$. Hence, the rate $j/4$ lies between $1\tfrac{1}{8}\%$ and $1\tfrac{1}{4}\%$. Interpolating, we have

$$.00125\begin{cases} & \begin{bmatrix} s_{\overline{40}|.0125} = 51.4896 \\ x\begin{cases} s_{\overline{40}|\frac{j}{4}} = 51.0000 \\ s_{\overline{40}|.01125} = 50.1668 \end{cases} \end{bmatrix} \begin{matrix} \\ .8332 \end{matrix} \end{cases} 1.3228$$

$$\frac{x}{.00125} = \frac{0.8332}{1.3228}, \quad x = 0.00079$$

$$\frac{j}{4} = 0.01125 + 0.00079 = 0.01204.$$

And $\qquad\qquad j = 0.04816 = 4.816\%$ (approximately).

This result may be checked by logarithms. We have

$$S = 100\,\frac{(1.01204)^{40} - 1}{0.01204}$$

$$\log 1.01204 = 0.0051977 \quad \text{(Table II)}$$
$$40 \log 1.01204 = 0.2079080$$
$$(1.01204)^{40} = 1.6140. \qquad \text{(Table I)}$$

And $\qquad\qquad S = 100\,\dfrac{(1.6140 - 1)}{0.01204}$

$$= \frac{61.40}{0.01204} = \$5,099.67.$$

This result is only 33 cents less than the \$5,100 and the rate 4.816% is accurate enough. If 7 place logarithms had been used to find the antilogarithm of 0.2079080, our result would have been \$5,099.80 which differs from the \$5,100.00 by only 20 cents.

Example 2. The present value of an annuity of \$400 per annum for 20 years is \$5,000. Find the interest rate.

Solution. Here, $R = \$400$, $m = p = 1$, $n = 20$, and $A = \$5,000$. Substituting $A\,$I2, Art. 31, we have

$$5,000 = 400\,\frac{1 - (1 + i)^{-20}}{i} = 400\,a_{\overline{20}|}.$$

Then $\qquad\qquad a_{\overline{20}|} = 12.5000.$

We now turn to Table VI and follow $n = 20$, until we come to a value just greater than 12.5000 and one just less than 12.5000. We find the value

13.0079 corresponding to 4½% and 12.4622 corresponding to 5%. Hence, the rate i lies between 4½% and 5%.

Therefore,
$$i = 0.045 + \frac{0.5079}{0.5457}(0.005)$$

$$= 0.045 + 0.00465$$

$$= 0.04965 = 4.97\% \text{ (approximately)}.$$

Example 3. A house is priced at $2,500 cash or for $50 a month in advance of 60 months. What is the effective rate of interest charged in the installment plan?

Solution. We have here an *annuity due* of 60 periods. Let us assume for convenience that the nominal rate is j converted 12 times a year. Then, $m = p = 12$, $R = \$600$, and $A' = \$2,500$. Substituting in $BII2$, Art. 31, we find

$$2{,}500 = 50\left(1 + \frac{1 - \left(1 + \frac{j}{12}\right)^{-59}}{\frac{j}{12}}\right)$$

$$= 50(1 + a_{\overline{59}|}).$$

Then
$$a_{\overline{59}|} = 49.0000.$$

Turning to Table VI, we find that when

$$\frac{j}{12} = \frac{7}{12}\%, \quad a_{\overline{59}|} = 49.7968;$$

when
$$\frac{j}{12} = \frac{3}{4}\%, \quad a_{\overline{59}|} = 47.5347.$$

Therefore,
$$\frac{j}{12} = 0.00583 + \frac{49.7968 - 49.0000}{49.7968 - 47.5347}(0.00167)$$

$$= 0.00583 + 0.00059 = 0.00642.$$

And
$$j = 0.07704 = 7.704\%. \quad \text{(Approximate nominal rate)}.$$

Checking by logarithms as in Example 1, we find

$$A' = \$2{,}499.14,$$

which is 86 cents less than the $2,500.00.

To find the effective rate, we have

$$(1 + i) = (1.00642)^{12} \qquad (4) \text{ Art. 16.}$$

$$\log 1.00642 = 0.0027792$$

$$12 \log 1.00642 = 0.0333504$$

$$(1.00642)^{12} = 1.07982 = (1 + i).$$

Therefore, $\qquad\qquad i = 0.07982 = 7.982\%.$

Exercises

1. At what rate of interest will an annuity of $500 a year amount to $25,000 in 25 years?

2. A house is offered for sale for $6,000 cash or $1,000 at the end of each year for the next 8 years. If the installment plan is used, what rate of interest is charged?

3. The cash price of an automobile is $1,150. A man is allowed $525 on his old car as a down payment. To care for the balance he pays $57.20 at the end of each month for 12 months. What rate of interest is charged? Use simple interest. [See p. 34.]

4. A man deposits $9,500 with a trust company now with the guarantee that he (or his heirs) is to receive $1,000 each year for 25 years, the first $1,000 to be paid at the end of 10 years. What effective rate of interest is the man allowed on his money?

35. The term of an annuity.—We illustrate by examples the method of finding the term of an annuity.

Example 1. In how many years will an annuity of $400 per year amount to $9,500, if the interest rate is $3\frac{1}{2}\%$ converted annually?

Solution. Here, $R = \$400$, $S = \$9,500$, and $i = 0.035$. Substituting in $AI1$, Art. 31, we have

$$9,500 = 400 \frac{(1.035)^n - 1}{0.035} = 400 s_{\overline{n}|}.$$

And $\qquad\qquad s_{\overline{n}|} = 9,500 \div 400 = 23.7500.$

We now turn to Table V and follow down the $3\frac{1}{2}\%$ column. We notice that when

$$n = 17, \quad s_{\overline{n}|} = 22.7050;$$

$$n = 18, \quad s_{\overline{n}|} = 24.4997.$$

It is evident that 18 payments of $400 will amount to more than $9,500. In fact, it will amount to $9,799.88, which is $299.88 more than is needed. Hence, $400 per year for 17 years and

$$\$100.12, (\$400.00 - \$299.88)$$

at the end of 18 years will amount to exactly $9,500.

Example 2. An individual buys a house for $5,000 paying $1,000 in cash. He agrees to pay the balance in installments of $500 at the end of each year. How long will it take to pay the $4,000 and interest at 6% converted annually?

Solution. Here, $A = \$4,000$, $R = \$500$, $m = p = 1$, and $i = 0.06$. Substituting in $A12$, Art. 31, we have

$$4,000 = 500\,\frac{1 - (1.06)^{-n}}{0.06} = 500a_{\overline{n}|}.$$

And
$$a_{\overline{n}|} = 8.0000.$$

We now turn to Table VI and follow down the 6% column. We notice that when

$$n = 11,\ a_{\overline{n}|} = 7.8869$$

$$n = 12,\ a_{\overline{n}|} = 8.3838.$$

Hence, the present value of 11 payments is less than $4,000 and the present value of 12 payments is more than $4,000. Then, it is evident that the debtor must make 11 full payments of $500 each and a 12th payment, at the end of 12 years, which is less than $500.

If no payments were made, the original principal of $4,000 would accumulate in 11 years to

$$4,000(1.06)^{11} = 4,000(1.89829856) = \$7,593.19.$$

However, if payments of $500 are made regularly for 11 years, they will accumulate to

$$500\,\frac{(1.06)^{11} - 1}{0.06} = 500(14.97164264) = \$7,485.82$$

Hence, just after the 11th payment, the balance on the principal is $7,593.19 − $7,485.82 = $107.37. That is, the debt could be cancelled by making an additional payment of $107.37 along with the 11th regular payment. However, if the balance is not to be paid until the end of the 12th year, the payment would be $107.37 plus interest on it for 1 year at 6%, or $107.37 + $6.44 = $113.81. Then, 11 payments of $500 and a partial payment of $113.81 made at the end of 12 years will settle the debt.

1. In how many years will an annuity of $750 amount to $10,000 if interest is at 6½%? Solve by interpolation.

2. Solve formula $AI1$, Art. 31, for n.

$$n = \frac{\log (iS + R) - \log R}{\log (1 + i)}.$$

3. Solve Exercise 1 by the formula given in Exercise 2.

4. A man borrows $3,000 and desires to repay principal and interest in installments of $400 at the end of each year. Find the number of full payments necessary and the size of the partial payment, if it is made 1 year after the last full payment is made, assuming an interest rate of 5%.

5. A man deposits $15,000 in a trust fund with the agreement that he is to receive $2,000 a year, beginning at the end of 10 years, until the fund is exhausted. If the trust company allows him 4% interest on his deposits, how many full payments of $2,000 will be paid and what will be the fractional payment paid at the end of the next year?

36. Finding the periodic payment.—In the early sections of this chapter we solved the problems of finding the amount and the present value of an annuity under given conditions when the periodic payment was known. Our results were summarized in Art. 31.

We are now about to attack the inverse problem, that of finding the periodic payment under given conditions, when the amount or the present value of the annuity is known. The solution requires no new formulas. We must merely solve the equations of Art. 31 for R or R/p according as the annuity is payable annually or p times a year. Consider the following examples.

Example 1. A man buys a house for $6,000 and pays $1,000 in cash. The remainder with interest is to be paid in 40 equal quarterly payments, the first payment being due at the end of three months. Find the quarterly payment if the interest rate is 6% converted annually.

Solution. Here, $A = \$5,000$, $n = 10$, $p = 4$, $i = 0.06$. Substituting in Art. 31, $BI2$, and solving for R, we have

$$R = 5,000 \frac{4[(1.06)^{\frac{1}{4}} - 1]}{1 - (1.06)^{-10}}$$

$$= \frac{5,000(0.05869538)}{1 - 0.55839478} \quad \text{[Tables IV and IX]}$$

$$= \$664.57, \text{ annual payment.}$$

Then, $\quad \dfrac{R}{4} = \$166.14$, quarterly payment.

Example 2. Solve Example 1, with the interest converted semi-annually.

Solution. Using $BII2$, Art. 31, we have

$$R = 5,000 \frac{4[(1.03)^{\frac{1}{2}} - 1]}{1 - (1.03)^{-20}}$$

$$= \frac{10,000 \cdot 2[(1.03)^{\frac{1}{2}} - 1]}{1 - (1.03)^{-20}}$$

$$R = \frac{10,000(0.02977831)}{1 - 0.55367575} \quad \text{[Tables IV and IX]}$$

$$= \frac{10,000(0.02977831)}{0.44632425} = \$667.19.$$

Then, $\dfrac{R}{4} = \$166.80$, quarterly payment.

Example 3. Solve Example 1, with the interest converted quarterly.

Solution. Here, $m = p = 4$, and $BII2$, Art. 31 gives us

$$\frac{R}{4} = 5,000 \frac{0.015}{1 - (1.015)^{-40}} = 5,000 \cdot \frac{1}{a_{\overline{40}|\cdot 015}}$$

$$= 5,000(0.03342710) \quad \text{[Table VII]}$$

$$= \$167.14, \text{ quarterly payment.}$$

Example 4. How much must be set aside semi-annually so as to have $10,000 at the end of 10 years, interest being at the rate of 5% converted annually?

Solution. Here, $S = \$10,000$, $n = 10$, $p = 2$, $i = 0.05$. Substituting in $BI1$, Art. 31, we have

$$R = 10,000 \frac{2[(1.05)^{\frac{1}{2}} - 1]}{(1.05)^{10} - 1}$$

$$= \frac{10,000(0.04939015)}{1.62889463 - 1} \quad \text{[Tables III and IX]}$$

$$= \$785.35, \text{ annual payment.}$$

Then, $\dfrac{R}{2} = \$392.67$, semi-annual payment.

Example 5. Solve Example 4, with the interest converted semi-annually.

Solution. Here, $m = p = 2$, the other conditions being the same as in Example 4. Substituting in BIII1, Art. 31, we have

$$\frac{R}{2} = 10{,}000 \frac{0.025}{(1.025)^{20} - 1} = 10{,}000 \cdot \frac{1}{s_{\overline{20}|.025}}$$

$$= 10{,}000(0.06414713 - 0.025) \quad \text{[Table VII]}$$

$$= 10{,}000(0.03914713) = \$391.47.$$

Example 6. Solve Example 4, with the interest converted quarterly.

Solution. Here, $m = 4$, the other conditions being the same as in Example 4. Substituting in BIII1, Art. 31, we have

$$R = 10{,}000 \frac{2[(1.0125)^{\frac{1}{2}} - 1]}{(1.0125)^{40} - 1}$$

$$= 20{,}000 \frac{(1.0125)^2 - 1}{0.0125} \cdot \frac{0.0125}{(1.0125)^{40} - 1}$$

$$= 20{,}000(2.01250000)(0.01942141) \quad \text{[Tables V and VII]}$$

$$= \$781.71, \text{ annual rent.}$$

Then, $\quad\quad \dfrac{R}{2} = \$390.86$, semi-annual payment.

Exercises

1. A man buys a farm for $10,000. He pays $5,000 cash and arranges to pay the balance with 5% interest converted semi-annually, by making equal payments at the end of each six months for 14 years. How much is the semi-annual payment?

2. How much must be set aside annually to accumulate to $5,000 in 8 years, if money is worth $4\frac{1}{2}\%$ converted semi-annually?

3. Solve Exercise 2, with the interest converted (a) annually, (b) quarterly.

4. In order to finance a school building costing $100,000 a city issues 20-year bonds which pay 5% interest, payable semi-annually. How much must be deposited, at the end of each six months, in a sinking fund which accumulates at $4\frac{1}{2}\%$ converted semi-annually, if the bonds are to be redeemed in full at the end of 20 years? What total semi-annual payment is necessary to pay the interest on the bonds and make the sinking fund payment?

5. Solve Exercise 4, with the interest on the sinking fund converted quarterly.

6. At the maturity of a $20,000 endowment policy, the policyholder may take the full amount in cash or leave the full amount with the insurance company to be paid to him in 40 equal quarterly payments, the first payment to be made at the end of three months. If 4% interest, converted quarterly, is allowed on all money left with the company, how much is the quarterly payment?

7. A building is priced at $25,000 cash. The owner agrees to accept $5,000 cash and the balance, principal and interest, in equal annual payments for 15 years. If the interest rate is 7% effective, what is the annual payment?

8. Solve Exercise 7, with the interest converted quarterly.

37. Perpetuities and capitalized cost.—*An annuity whose payments continue forever is defined as a perpetuity.* It is evident that the *amount* of such an annuity increases indefinitely, but the present value is definite. The symbol A_∞, will denote the present value of a perpetuity of R dollars per annum, payable annually.

It is evident that the interest on A_∞ for one year at nominal rate (j, m) must equal R.

Hence,
$$A_\infty \left(1 + \frac{j}{m}\right)^m - A_\infty = R,$$

and
$$A_\infty = \frac{R}{\left(1 + \dfrac{j}{m}\right)^m - 1},$$

or
$$A_\infty = \frac{R}{\dfrac{j}{m}} \cdot \frac{\dfrac{j}{m}}{\left(1 + \dfrac{j}{m}\right)^m - 1} = \frac{Rm}{j} \cdot \frac{1}{s_{\overline{m}|\frac{j}{m}}}. \qquad (29)$$

When $m = 1$, $j = i$, and (29) reduces to

$$A_\infty = \frac{R}{i}. \qquad (29')$$

Example 1. Find the present value of a perpetuity of $500 per annum, if money is worth 4% converted annually.

Solution. Here, $R = \$500$, $i = 0.04$.

Then,
$$A_\infty = \frac{500}{0.04} = \$12,500. \quad [\text{Formula } (29')]$$

Example 2. Solve Example 1, with the interest converted quarterly.

Solution. Here, $R = \$500$, $j = 0.04$, and $m = 4$. Substituting in (29), we have

$$A_\infty = \frac{500}{0.01} \cdot \frac{0.01}{(1.01)^4 - 1} = 50,000 \frac{0.01}{(1.01)^4 - 1} = 50,000 \cdot \frac{1}{s_{\overline{4}|.01}}$$

$$= 50,000(0.24628109) \quad \text{[Table VII]}$$

$$= \$12,314.05.$$

There are times when a perpetuity must provide for payments at intervals longer than a conversion period. The symbol $A_{\infty,\,r}$, will denote the present value of a perpetuity of C dollars payable every r years.

It is evident that the compound interest on $A_{\infty,\,r}$, for r years at rate j converted m times a year must equal C.

Hence,
$$A_{\infty,\,r}\left(1 + \frac{j}{m}\right)^{mr} - A_{\infty,\,r} = C,$$

and
$$A_{\infty,\,r} = \frac{C}{\left(1 + \dfrac{j}{m}\right)^{mr} - 1},$$

or
$$A_{\infty,\,r} = \frac{C}{\dfrac{j}{m}} \cdot \frac{\dfrac{j}{m}}{\left(1 + \dfrac{j}{m}\right)^{mr} - 1} = \frac{Cm}{J} \cdot \frac{1}{s_{\overline{mr}|\frac{j}{m}}}. \tag{30}$$

If $m = 1, j = i$, and
$$A_{\infty,\,r} = \frac{C}{i} \cdot \frac{1}{s_{\overline{r}|i}} \tag{30'}$$

Example 3. What is the present value of a perpetuity of $\$2,000$ payable every 4 years, if money is worth 5% converted annually?

Solution. Here, $C = \$2,000$, $r = 4$, $i = 0.05$. Substituting in (30'), we have

$$A_{\infty,\,4} = \frac{2,000}{0.05} \cdot \frac{0.05}{(1.05)^4 - 1} = 40,000 \cdot \frac{1}{s_{\overline{4}|.05}}$$

$$= 40,000(0.23201183) \quad \text{[Table VII]}$$

$$= \$9,280.47.$$

Example 4. Solve Example 3, with the interest converted semi-annually.

Solution. Here, $C = \$2,000$, $j = 0.05$, $m = 2$, and $r = 4$. We have

$$A_{\infty, 4} = \frac{2,000}{0.025} \cdot \frac{0.025}{(1.025)^8 - 1} \quad \text{[Formula (30)]}$$

$$= 80,000 \frac{0.025}{(1.025)^8 - 1} = 80,000 \cdot \frac{1}{s_{\overline{8}|.025}}$$

$$= 80,000(0.11446735) = \$9,158.39. \quad \text{[Table VII]}$$

Example 5. A section of city pavement costs $50,000. Its life is 25 years. Find the amount of money required to build it now and to replace it every 25 years, indefinitely, if money is worth 4% converted annually.

Solution. It is evident that the amount required to replace the pavement indefinitely is the present value of a perpetuity of $50,000 payable every 25 years at 4%.

$$\therefore A_{\infty, 25} = \frac{50,000}{0.04} \cdot \frac{0.04}{(1.04)^{25} - 1} \quad \text{[Formula (30')]}$$

$$= 1,250,000(0.02401196) \quad \text{[Table VII]}$$

$$= \$30,014.95.$$

Hence, the amount required to build the pavement plus the amount to replace it indefinitely equals

$$\$50,000 + \$30,014.95 = \$80,014.95.$$

This amount is called the *capitalized cost*. That is, *the capitalized cost is the first cost plus the present value of a perpetuity required to renew the project indefinitely.*

If we let K stand for the capitalized cost of an article whose first cost is C, and which must be renewed every r years at the cost C, we have

$$K = C + \frac{C}{\dfrac{j}{m}} \cdot \frac{\dfrac{j}{m}}{\left(1 + \dfrac{j}{m}\right)^{mr} - 1}$$

$$= C + \frac{C}{\left(1 + \dfrac{j}{m}\right)^{mr} - 1} = C \frac{\left(1 + \dfrac{j}{m}\right)^{mr}}{\left(1 + \dfrac{j}{m}\right)^{mr} - 1}$$

$$= \frac{C}{\dfrac{j}{m}} \cdot \frac{\dfrac{j}{m}}{1 - \left(1 + \dfrac{j}{m}\right)^{-mr}} = \frac{Cm}{j} \cdot \frac{1}{a_{\overline{mr}|\frac{j}{m}}}. \tag{31}$$

If $m = 1, j = i,$

then
$$K = \frac{C}{i} \cdot \frac{1}{a_{\bar{n}|i}}$$
(31')

Example 6. An automobile costs $1,000 and will last 7 years when it must be replaced at the same cost. Another automobile, which would serve the same purpose and would last 10 years, could be purchased. What could one afford to pay for the second automobile if it is to be as economical in the long run as the first, assuming money worth 5%?

Solution. When somebody says that a certain article is just as economical (cheap) in the long run as another article, he simply means that the two articles have the same capitalized cost.

The first automobile has a capitalized cost of

$$\frac{1,000}{0.05} \cdot \frac{0.05}{1 - (1.05)^{-7}}. \quad \text{[Formula (31')]}$$

If we let x stand for the cost of the second automobile, it will have a capitalized cost of

$$\frac{x}{0.05} \cdot \frac{0.05}{1 - (1.05)^{-10}}. \quad \text{[Formula (31')]}$$

Assuming that the two automobiles are equally economical, we have

$$\frac{x}{0.05} \cdot \frac{0.05}{1 - (1.05)^{-10}} = \frac{1,000}{0.05} \cdot \frac{0.05}{1 - (1.05)^{-7}}$$

and
$$x = 1,000 \frac{1 - (1.05)^{-10}}{0.05} \cdot \frac{0.05}{1 - (1.05)^{-7}}$$

$$= 1,000(7.72173493)(0.17281982) \quad \text{[Tables VI, VII]}$$

$$= \$1,334.47.$$

That is, one can afford to pay $1,334.47 for the automobile that lasts 10 years, or $334.47 more, for the additional 3 years of service.

We shall now find the additional cost w required to increase the life of a given article x years assuming money worth $i\%$.

Let C = original cost of an article to last n years. Its capitalized cost is

$$\frac{C}{i} \cdot \frac{i}{1 - (1 + i)^{-n}}.$$

Let $C + w =$ cost of an article to last $n + x$ years. Its capitalized cost is

$$\frac{C + w}{i} \cdot \frac{i}{1 - (1 + i)^{-(n+x)}}$$

Equating capitalized costs, we have

$$\frac{C + w}{i} \cdot \frac{i}{1 - (1 + i)^{-(n+x)}} = \frac{C}{i} \cdot \frac{i}{1 - (1 + i)^{-n}}.$$

The student may solve the above equation for w and get

$$w = C \frac{i}{(1 + i)^{x} - 1} \cdot \frac{1 - (1 + i)^{-x}}{i}.$$

$$= C \frac{a_{\overline{x}|i}}{s_{\overline{n}|i}} \tag{32}$$

If the interest rate is j converted m times per year, (32) may be written

$$w = C \frac{\dfrac{j}{m}}{\left(1 + \dfrac{j}{m}\right)^{mn} - 1} \cdot \frac{1 - \left(1 + \dfrac{j}{m}\right)^{-mx}}{\dfrac{j}{m}} \tag{32'}$$

Example 7. A cross tie costs \$1.00 and will last 10 years. The life of the tie can be extended to 18 years by treating with creosote. If money is worth 5%, how much could one afford to spend for the treatment?

Solution. Here, $C = \$1.00$, $n = 10$, $x = 8$, and $i = 0.05$. From (32) we have

$$w = 1.00 \cdot a_{\overline{8}|.05} \cdot \frac{1}{s_{\overline{10}|.05}}$$

$$= (0.07950458)\,(6.46321276) \qquad \text{[Tables VI, VII]}$$

$$= \$0.51.$$

That is, 51¢ could profitably be spent to treat the tie, if the service life would be extended 8 years.

Exercises

1. What amount would a railroad company be justified in expending per tie to extend the life of cross ties costing \$1.50 each from 12 to 20 years, money being worth 4%?

2. A hospital receives an annual income of \$120,000 as a perpetuity from a trust fund. What is the value of this perpetuity, money being worth 5% effective?

3. Solve Exercise 2, if the interest rate were 5% converted quarterly.

4. A railroad company has been paying a watchman $1,600 a year to guard a crossing. The company decides to build an overhead crossing at a cost of $22,000. If the overhead crossing must be rebuilt every 35 years at the same cost, how much does the company save by building it? Assume money worth 5%.

5. An office building is erected at a cost of $100,000. It requires a watchman at an annual salary of $1,500, and $4,000 for repairs and renovation every 8 years. It must be rebuilt every 80 years at the original cost. How much money is required now to provide for its construction, maintenance, guarding and rebuilding, assuming money worth 3%? (Hint: Every 80 years when the building is rebuilt, the $4,000 allowed for repairs and renovation is not needed. This amount may be applied on the $100,000 for rebuilding, thereby reducing it to $96,000.)

6. A state highway commission has a certain road graded and ready for surfacing. It may be graveled at a cost of $2,000 per mile, or paved at a cost of $10,000 per mile. It will cost $200 per year to maintain the gravel road and it will need regraveling every 8 years at the original cost. The maintenance cost of the pavement is negligible and it will need repaving only every 40 years at the original cost. If the cost for clearing the road bed of the old paving is $1,000, which type of road is more economical, assuming that the state can borrow money at 4%?

38. Increasing and decreasing annuities.—A sequence of periodic payments in which each payment exceeds by a fixed amount the preceding payment is called an *increasing annuity*. If each payment is less by a fixed amount than the preceding, the sequence is called a *decreasing annuity*.

Consider the following examples.

Example 1. Find the amount and the present value of a decreasing annuity with payments of $250, $200, $150, $100, $50, at the ends of the next five years if money is worth 4%.

Solution. Here is the picture.

```
        250        200        150        100         50
  |------+----------+----------+----------+----------+
  0      1          2          3          4          5
```
These payments are equivalent to the following five ordinary annuities, superimposed: (1) $50 a year for 5 years; (2) $50 a year for 4 years; (3) $50 a year for 3 years; (4) $50 a year for 2 years; (5) $50 a year for 1 year. These annuities are exhibited in the following diagram.

```
        50
        50         50
        50         50         50
        50         50         50         50
        50         50         50         50         50
  |------+----------+----------+----------+----------+
  0      1          2          3          4          5
```
To find the amount of a decreasing annuity, we first find its present value. The present value of the given decreasing annuity is

$$A = 50\, a_{\overline{1}|} + 50\, a_{\overline{2}|} + 50\, a_{\overline{3}|} + 50 a_{\overline{4}|} + 50\, a_{\overline{5}|}$$

$$= 50[a_{\overline{1}|} + a_{\overline{2}|} + a_{\overline{3}|} + a_{\overline{4}|} + a_{\overline{5}|}]$$

$$= 50\left[\frac{5 - a_{\overline{5}|.04}}{.04}\right] \quad \text{Exercise 8, Art. 28}$$

$$= 1250(5 - 4.4518\ 2233)$$

$$= \$685.222.$$

The amount of this annuity is clearly

$$S = A(1.04)^5 = 685.222(1.2166\ 5290)$$

$$= \$833.68.$$

Example 2. Find the amount and the present value of an increasing annuity with payments of \$50, \$100, \$150, \$200, \$250 at the ends of the next five years if money is worth 4%.

Solution. Here is the picture.
These payments are equivalent to five ordinary annuities that we exhibit in the following diagram.
The amount of this increasing annuity is

$$S = 50\, s_{\overline{1}|} + 50\, s_{\overline{2}|} + 50\, s_{\overline{3}|} + 50\, s_{\overline{4}|} + 50\, s_{\overline{5}|}$$

$$= 50[s_{\overline{1}|} + s_{\overline{2}|} + s_{\overline{3}|} + s_{\overline{4}|} + s_{\overline{5}|}]$$

$$= 50\left[\frac{(1.04)\, s_{\overline{5}|.04} - 5}{.04}\right] \quad \text{Exercise 7, Art. 28}$$

$$= 1250[(1.04)\,(5.4163\ 2256) - 5]$$

$$= \$791.22.$$

The present value of this increasing annuity is clearly

$$A = S(1.04)^{-5} = 791.22(0.8219\ 2711)$$
$$= \$650.33.$$

Exercises

1. If money is worth 5%, find the amount and the present value of the increasing annuity pictured on the diagram.

	100	200	300	400	500	600	700
0	1	2	3	4	5	6	7 years

2. If money is worth 5%, find the amount and the present value of the decreasing annuity pictured on the diagram.

	700	600	500	400	300	200	100
0	1	2	3	4	5	6	7 years
Problems

1. Show that formulas (12), (13), and (26) are special cases of formula (27). Follow method on page 76.

2. In order to accumulate $20,000 in 14 years, how much must be deposited in a savings bank at the end of each year, if the interest is converted annually at 4%?

3. An automobile is bought for $400 cash and $62 a month for 15 months. What is the equivalent cash price if money is worth 7% converted monthly?

4. Find the rate of interest if an annuity of $700 a year amounts in 15 years to $15,000.

5. The proceeds of a $5,000 insurance policy is to be paid in monthly installments of $50 each. If money is worth 5% converted monthly, find the number of monthly payments. The first payment is made at the end of the first month.

6. A man buys a house for $8,000, paying $2,000 cash. He arranges for the balance, principal, and interest at 6%, to be paid in 60 monthly installments. Find the size of each installment if the interest is converted monthly.

7. A son is to receive $1,000 a year for 12 years, the first payment being due 6 years hence. Find the present value of the son's share assuming 5% interest converted annually.

8. The beneficiary of an insurance policy is offered $15,000 in cash or equal annual payments for 12 years, the first payment being due at once. Find the size of the annual payments if money is worth 4%.

9. A wooden bridge costs for construction $22,500, and requires rebuilding every 20 years. How much additional money can be profitably expended for the erection of a concrete bridge instead, if money is worth 5% and the service life is extended to 40 years?

10. A building costs $40,000 and has a life of 50 years. If it requires $2,000 every 5 years for upkeep, what endowment should be provided at the time it is built to construct it, rebuild it every 50 years and provide for its upkeep? At the end of every 50 years the $2,000 allowed for upkeep may be applied towards the reconstruction cost. Assume money worth 4%.

11. How much can a railroad company afford to pay to abolish a grade crossing which is guarded at a cost of $1,000 per year, when money is worth 5% converted semi-annually?

12. A certain machine costs $2,000 and must be replaced every 12 years at the same cost. A certain device may be added to the machine which will double its output, but the machine must then be replaced every 10 years. Assuming money worth 4%, what is the value of the device?

13. $100 is deposited in a savings bank at the end of every six months for 10 years. During the first 6 years 3%, converted semi-annually, was allowed but during the last 4 years the rate was reduced to $2\frac{1}{2}\%$, converted semi-annually. Find the amount on deposit at the end of 10 years.

14. Derive formula (32), Art. 37.

15. An income of $10,000 at the end of each year is equivalent to what income at the end of every 5 years, assuming money worth 5% converted semi-annually?

16. Solve Exercise 15, with the interest converted (a) annually, (b) quarterly.

17. A building has just been completed at a cost of $250,000. It is estimated that $2,500 will be needed at the end of every two years for repairs, and that every 15 years there must be renovation to the extent of $10,000, and that the building will have a service life of 60 years with a salvage value of $20,000. Find what equal annual amount should be set aside at 4% interest to cover repairs, renovations, and replacements. How should the $2,500 repair fund and the $10,000 renovation fund be used at the end of every 60 years?

18. A man borrowed $10,000 with the understanding that it be repaid by 20 equal annual installments including principal and interest at 6% annually. Just after the 10th equal annual payment had been made the creditor agreed to reduce the principal by $1,000 and reduce the rate to $4\frac{1}{2}\%$. Find the annual payment for the first 10 years and the annual payment for the last 10 years.

19. A mortgage for $5,000 was given with the understanding that it might be repaid, principal and interest, by 15 equal annual payments. Find the annual payment if the interest rate was 7% for the first 8 years and 5% for the last 7 years.

20. A person pays $12,500 into a trust fund now with the guarantee that he or his heirs will receive equal annual payments for 30 years, the first payment to be made at the end of 7 years. If the trust fund draws 4% interest, find the equal annual payment.

21. A perpetuity of $25,000 a year is divided between a man's daughter and a university. The daughter receives the entire income until she has received as her share one half the present value of the perpetuity. Find the number of full payments she receives and the size of the last payment, if money is worth 5% converted annually.

22. A man pays $6,000 into a trust fund and receives $500 at the end of each year for 20 years. What rate of interest converted annually did he earn on his money?

23. At his son's birth a father set aside a sum sufficient to pay the boy $1,000 a

year for 7 years, the first $1,000 to be paid on his 18th birthday. What sum was set aside, if money was worth 4% converted semi-annually?

24. The amount of an annuity of $800 per year is $20,000 and the present value is $9,235. Find the rate of interest.

25. A man buys a piano for $300 and pays $50 cash. The balance is to be paid for at $12.50 at the end of each month for 24 months. What effective rate of interest does the purchaser pay? (Hint: Assume that the interest is converted monthly and find the nominal rate. Then find the effective rate.)

26. Is it economical to replace a machine which costs $500 and lasts 8 years by one that costs $650 and lasts 12 years? Assume that the annual running expense of each machine is the same and that money is worth 5%. Also assume that the two machines have the same output.

27. A person considers replacing a machine which costs $400 and lasts 6 years by a machine which costs $750 and answers the same purpose as the other machine. If the exchange is to be economical, how long should the new machine last? Assume that the annual running expense is the same for each machine and that money is worth 4%.

28. Derive formula (29') by setting up a series and finding its sum. From (29') derive (29).

29. Derive formula (30') by setting up a series and finding its sum. From (30') derive (30).

30. Derive formula (29') from (5) by showing that $\lim\limits_{n \to \infty} R\, a_{\overline{n}|i} = R/i$.

31. If money is worth ($j = .04$, $m = 2$), find the present value of the decreasing annuity: $5,000, $4,500, \cdots $500 payable semi-annually.

32. If money is worth ($j = .04$, $m = 2$), find the present value of the increasing annuity: $500, $1,000, \cdots $5,000 payable semi-annually.

33. State a problem for which the answer would be

$$1000 \frac{(1.01)^{40} - 1}{(1.01)^4 - 1}.$$

34. State a problem for which the answer would be

$$500 \frac{1 - (1.025)^{-30}}{(1.025)^2 - 1}.$$

35. State a problem for which the answer would be

$$500 \frac{(1.02)^{24} - 1}{(1.02)^2 - 1} (1.02)^{10}.$$

36. In an increasing annuity, R is paid at the end of the first year, $2R$ at the end of the second year, and so on for n years. Show that

$$S = \frac{R}{i} [s_{\overline{n}|}(1 + i) - n],$$

$$A = \frac{R}{i} [(1 + i)a_{\overline{n}|} - n(1 + i)^{-n}].$$

37. In a decreasing annuity nR is paid at the end of the first year, $(n-1)R$ at the end of the second year, and so on for n years. Show that

$$S = \frac{R}{i}[n(1+i)^n - s_{\overline{n}|}],$$

$$A = \frac{R}{i}[n - a_{\overline{n}|}].$$

Review Problems *

1. $1,000

<div align="right">Harrisburg, Pennsylvania,
July 12, 1945.</div>

Four months after date I promise to pay Joe Brown, or order, one thousand dollars with interest from date at 5%.

<div align="right">(Signed) JOHN JONES.</div>

(a) Three months after date Brown sold the note to Bank B who discounted the note at 6% discount rate. What did Brown receive for the note?

(b) Immediately after purchasing the above note, Bank B sold the note to a Federal Reserve Bank at a re-discount rate of 4%. How much did Bank B gain on the transaction?

2. Same note as in Problem 1. Would it have been to Brown's advantage to have sold the note to friend C, to whom money was worth 6%, rather than to Bank B?

3. I bought a bill of lumber from the Jones Lumber Company who quoted the terms "net 60 days or 2% off for cash." What nominal rate of interest, j_6, could I afford to pay to borrow money to take advantage of the discount? What effective rate?

4. A note for $1,000 with interest at $(j = .06, m = 2)$, and another for $800 with interest at $(j = .05, m = 2)$, both due in 3 years, were purchased to net 7% effective. How much was paid for them?

5. A bank pays 4% interest on time deposits and loans money at 6% discount rate. What is the annual profit on time deposits amounting to $100,000?

6. The Jones Lumber Company estimates that they can earn 3% a month on their money. If I buy a $1,000 bill of lumber from them, what amount of discount can they afford to offer me to encourage immediate settlement in lieu of $1,000 at the end of the month? What is the nominal rate of discount, f_{12}, that they can afford to offer?

7. A son is now 10 years old. The father wishes to provide now for the college and professional education of the son by depositing the proper amount with a trust company that pays $(j = .04, m = 2)$ on funds. It is estimated that the son will need $1,000 a year for 7 years, the first payment to be made when the son is 18 years of age. Find the amount of the deposit.

8. A man owes a $6,000 balance on a home. The balance is at $(j = .06, m = 2)$. The man agrees to pay the balance with payments of $300 at the end of each half year. After how many payments will the balance be paid in full? What is the amount of the final partial payment?

9. A man at the age of 50 invests $20,000 in an annuity payable to him if living (to his estate if he is dead) in equal monthly installments over a period of 15 years, the first installment to be due at the end of the first month after he reaches 65. On a $3\frac{1}{2}$% basis, what is the monthly installment that he receives?

10. A man bought a refrigerator for $250 paying $50 down and the balance in 12 monthly installments of $20 each. What rate of interest does the purchaser pay? [Use simple interest.]

* For additional review problems, see end of this book.

CHAPTER IV

SINKING FUNDS AND AMORTIZATION

39. Sinking funds.—When an obligation becomes due at some future date, it is usually desirable to provide for its payment by accumulating a fund with periodic contributions, together with interest earnings. *Such an accumulated fund is called a sinking fund.*

Example. A debt of $6,000 is due in 5 years. A sinking fund is to be accumulated at 5%. What sum must be deposited in the sinking fund at the end of each year to care for the principal when due?

Solution. Here, $S = \$6,000$, $n = 5$, and $i = 0.05$. Since $m = p = 1$, we have from A I1, Art. 31,

$$R = 6{,}000\,\frac{0.05}{(1.05)^5 - 1} = 6{,}000 \cdot \frac{1}{s_{\overline{5}|.05}}$$

$$= 6{,}000\,(0.18097480) \text{ [Table VII]}$$

$$= \$1{,}085.85.$$

The amount in the sinking fund at any particular time may be shown by a schedule known as an *accumulation schedule*. The following is the schedule for the above problem:

Years	Annual Deposit	Interest on Fund	Total Annual Increase	Value of Fund at End of Each Year
1	$1,085.85		$1,085.85	$1,085.85
2	1,085.85	$ 54.29	1,140.14	2,225.99
3	1,085.85	111.30	1,197.15	3,423.14
4	1,085.85	171.16	1,257.01	4,680.15
5	1,085.85	234.01	1,319.86	6,000.01

40. Amortization.—Instead of leaving the entire principal of a debt standing for the term to be cancelled by a sinking fund, we may consider any payment over what is needed to pay interest on the principal to be

applied at once toward liquidation of the debt. As the debt is being paid off, a smaller amount goes towards the payment of interest, so that with a uniform payment per year, a greater amount goes towards the payment of principal. This method of extinguishing a debt is called the method of *amortization of principal.*

Example. Consider a debt of $2,000 bearing 6% interest converted annually. It is desired to repay this in 8 equal annual installments, including interest. Find the annual installment.

Solution. Here, $A = \$2,000$, $n = 8$, $i = 0.06$, $m = p = 1$. Substituting in $A12$, Art. 31, we have

$$R = 2,000 \, \frac{0.06}{1 - (1.06)^{-8}} = 2,000 \cdot \frac{1}{a_{\overline{8}|.06}}$$

$$= 2,000 \, (0.16103594) \text{ [Table VII]}$$

$$= \$322.07.$$

The interest for the first year will be $120; hence $202.07 of the first payment would be used for the reduction of principal, leaving $1,797.93 due on principal at the beginning of the second year. The interest on this amount is $107.88; hence, the principal is reduced by $214.19, leaving $1,583.74 due on principal at the beginning of the third year, and so on. This process may be continued by means of the following schedule known as an *amortization schedule:*

Year	Principal at Beginning of Year	Annual Payment	Interest at 6%	Principal Repaid
1	$2,000.00	$322.07	$120.00	$202.07
2	1,797.93	322.07	107.88	214.19
3	1,583.74	322.07	95.02	227.05
4	1,356.69	322.07	81.40	240.67
5	1,116.02	322.07	66.96	255.11
6	860.91	322.07	51.65	270.42
7	590.49	322.07	35.43	286.64
8	303.85	322.07	18.23	303.84
	$9,609.63		$576.57	$1,999.99

Such a schedule gives us the amount remaining due on the principal at the beginning of any year during the amortization period. The principal

at the beginning of the last year should equal the last principal repaid, and the sum of the principals repaid should equal the original principal.

Exercises

1. Find the annual payment that will be necessary to amortize in 10 years a debt of $2,500, bearing interest at 8% converted annually. Construct a schedule.

2. A mortgage of $5,000 is due in 8 years. A man wishes to take care of this principal when due by depositing equal amounts at the end of each year in a sinking fund which pays 5% interest. Find the annual deposit and check by an accumulation schedule.

3. A man owes $10,000 and agrees to pay it in 10 equal annual installments. Find the amount of each installment, allowing 6% for interest. Check by an amortization schedule.

4. A farmer buys a farm for $10,000. He has $6,000 to pay down and secures a federal farm loan for the balance to be amortized in 30 years at 5%. Find the annual payment and build up a schedule for the first 10 years.

5. In order to construct a filtering plant a city votes bonds for $50,000 which bear 6% interest, payable semi-annually. A city ordinance requires that a sinking fund be established to retire the bonds when they mature in 15 years. What semi-annual deposit must be made into the sinking fund, if it accumulates at 4%, converted semi-annually? What is the total semi-annual expense for the city?

6. A mortgage for $1,000 was given and it was agreed that it might be repaid, principal and interest, by 5 equal annual payments. Build up an amortization schedule if the interest rate is to be 5% for the first two years and 4% for the last three years.

41. Book value.—The book value of an indebtedness at any time may be defined as the difference between the original debt and the amount in the sinking fund at that time. Thus, in the example of Art. 39, we see that the book value of the debt at the end of the third year is $2,576.86, ($6,000 − $3,423.14). If the debt is being amortized, then the book value of the debt at the beginning of any year is the outstanding principal at that time. Thus, in the example of Art. 40, we observe that the book value of the debt at the beginning of the fourth year (at the end of the third year just after the third payment has been made) is $1,356.69. The subject of book value will be discussed further in connection with depreciation and valuation of bonds.

42. Amount in the sinking fund at any time.—To find the amount in the sinking fund at the end of k payment periods, $k < np$, we have only to find the accumulated value of an annuity of annual rent R for k payment periods by using the appropriate formula of Art. 31.

Example 1. Find the amount in the sinking fund of the Example of Art. 39, at the end of 4 years.

Solution.   Here, $R = \$1,085.85$, $k = 4$, $m = p = 1$, and $i = 0.05$. Hence, using AI1, Art. 31, the amount is given by

$$S_{\overline{4}|} = 1,085.85 \, \frac{(1.05)^4 - 1}{0.05} = 1,085.85 \cdot s_{\overline{4}|.05}$$

$$= 1,085.85 \, (4.31012500) \text{ [Table V]}$$

$$= \$4,680.15,$$

which checks with the amount given in the sinking fund schedule for the fourth year.

Example 2.   A debt of \$3,000 is due in 12 years.   A sinking fund is created by making equal annual payments.   If the interest rate is 5% converted annually, find the annual payment and the amount in the sinking fund just after the eighth annual payment has been made.

Solution.   Here, $S = \$3,000$, $n = 12$, $i = 0.05$, $k = 8$, $p = m = 1$.

$$R = 3,000 \, \frac{0.05}{(1.05)^{12} - 1} = \$188.48,$$

and $$S_{\overline{8}|} = 188.48 \, \frac{(1.05)^8 - 1}{0.05} = \$1,799.82.$$

Hence, the amount in the sinking fund at the end of 8 years is **\$1,799.82.**

43. Amount remaining due after the kth payment has been made.— When loans are paid by the amortization process it is necessary at times to know the amount of indebtedness (book value) after a certain number of payments have been made.   After k payments of R/p dollars have been made there remain $(np - k)$ payments and these remaining payments form an annuity whose *present value is exactly the amount due on the debt* after the kth payment has been made, and the debt could be cancelled by paying this present value.

Example 1.   Find the amount of unpaid principal just after making the fifth payment in the Example of Art. 40.

Solution.   Here, $R/p = \$322.07$, $n = 8$, $i = 0.06$, $m = p = 1$, and $k = 5$.   We have three payments remaining.   Hence

$$A_{\overline{3}|} = 322.07 \, \frac{1 - (1.06)^{-3}}{0.06} \text{ [Formula } A\text{I2, Art. 31]}$$

$$= 322.07 \, (2.67301195) \text{ [Table VI]}$$

$$= \$860.90.$$

This checks with the value given in the amortization schedule for the principal at the beginning of the 6th year (just after the fifth payment has been made).

Example 2. A debt of \$2,500 is to be amortized by 7 annual installments with interest at 6%. Find the amount unpaid on the principal just after making the fifth annual payment.

Solution. Here, $A = \$2,500$, $n = 7$, $k = 5$, $m = p = 1$, and $i = 0.06$. We have, using $A12$, Art. 31,

$$R = 2,500 \frac{0.06}{1 - (1.06)^{-7}} = \$447.84.$$

And

$$A_{\overline{2}|} = 447.84 \frac{1 - (1.06)^{-2}}{0.06}$$

$$= 447.84 \,(1.83339267) = \$821.06.$$

Hence, the amount unpaid on the principal at the end of the fifth year or just at the beginning of the sixth year is \$821.06.

Exercises

1. A man has been paying off a debt of \$2,800 principal and interest in 20 equal quarterly payments with interest at 5% converted quarterly. At the time of the 13th payment what amount is necessary to make the payment that will extinguish the entire debt?

2. In order to pay a mortgage of \$5,000 due in 7 years, a man pays into a sinking fund equal amounts at the end of each month. If the sinking fund pays 6% interest converted monthly, how much has he accumulated at the end of 5 years?

3. A man owes \$4,000, which is to be paid, principal and interest, in 10 equal annual payments, the first payment falling due at the end of the first year. If the interest rate is 6%, find the balance due on the debt just after the 6th payment is made.

4. A building and loan association sells a house for \$7,500, collecting \$1,500 cash. It is agreed that the balance with interest is to be paid by making equal payments at the end of each month for 10 years. If the interest rate is 7%, converted monthly, find the monthly payment. What equity does the purchaser have in the house just after making the 50th payment? What is his equity after the 70th payment has been made?

5. A person owes a debt of \$8,000, bearing 5% interest, which must be paid by the end of 10 years but may be paid at the end of any year after the fourth. He pays into a sinking fund equal amounts at the end of each year, which will accumulate to \$8,000 at the end of 10 years. Just after making the 7th payment into the sinking fund, how much additional money would be required to pay the debt in full, if the sinking fund accumulates at 5%.

44. The amortization and sinking fund methods compared.—We shall make this comparison by discussing a problem.

Problem. Let us consider a debt of principal $A_{\overline{np}|}$ which is due in n years and draws interest at rate r payable p times a year.

Discussion. This debt may be amortized by making np equal payments direct to the creditor, or it may be cared for by the sinking fund method.

If the amortization method is used the periodic payment will be

$$R/p = A_{\overline{np}|} \frac{\dfrac{r}{p}}{1 - \left(1 + \dfrac{r}{p}\right)^{-np}}. \tag{1}$$

Formula (1) gives us the total periodic expense, if the method of amortization is used.

It is easily seen that, since $\dfrac{1}{a_{\overline{n}|}} = i + \dfrac{1}{s_{\overline{n}|}}$,

$$\frac{\dfrac{r}{p}}{1 - \left(1 + \dfrac{r}{p}\right)^{-np}} = \frac{r}{p} + \frac{\dfrac{r}{p}}{\left(1 + \dfrac{r}{p}\right)^{np} - 1},$$

and (1) may be written

$$R/p = A_{\overline{np}|}\left(\frac{r}{p}\right) + A_{\overline{np}|} \frac{\dfrac{r}{p}}{\left(1 + \dfrac{r}{p}\right)^{np} - 1}. \tag{2}$$

If the sinking fund method is used, the interest at rate r payable p times a year is paid direct to the creditor and a fund to care for the principal when it becomes due n years from now is created by depositing equal payments p times a year into a sinking fund which accumulates at rate j converted p times a year. If this method is used, the total expense per period will be the sum of the periodic interest and the periodic payment into the sinking fund and is given by

$$E = A_{\overline{np}|}\left(\frac{r}{p}\right) + A_{\overline{np}|} \frac{\dfrac{j}{p}}{\left(1 + \dfrac{j}{p}\right)^{np} - 1}. \tag{3}$$

Now, if the sinking fund rate is the same as the interest rate on the debt $(j = r)$, then E of (3) is the same as R/p of (2). That is, when $j = r$, the periodic expense is the same by either plan, and the amortization method may be considered a special case of the sinking fund method where the creditor has charge of the sinking fund money and allows the same rate of interest on it that he charges on the debt.

If the sinking fund rate is less than the rate on the debt, that is, if $j < r$, then $\dfrac{1}{s_{\overline{np}|} \text{ at } j/p} > \dfrac{1}{s_{\overline{np}|} \text{ at } r/p}$ and E in (3) is greater than R/p in (2). That is, the sinking fund method is more expensive for the debtor than the amortization method.

If $j > r$, then $\dfrac{1}{s_{\overline{np}|} \text{ at } j/p} < \dfrac{1}{s_{\overline{np}|} \text{ at } r/p}$ and E is less than R/p. That is, the sinking fund method is less expensive for the debtor than the amortization method.

Example 1. A debt of $10,000, with interest at 6%, payable semi-annually, is due in 10 years. Find the semi-annual expense if it is to be cared for by the amortization method.

Solution. Here, $A_{\overline{np}|} = \$10,000$, $r = 0.06$, $p = 2$, and $n = 10$. We have

$$R/2 = 10,000 \frac{0.03}{1 - (1.03)^{-20}} \quad \text{[Formula (1)]}$$

$$= 10,000 \, (0.06721571) \quad \text{[Table VII]}$$

$$= \$672.16.$$

Example 2. Find the semi-annual expense in Example 1, if a sinking fund is accumulated at $(j = .05, p = 2)$.

Solution. Here, $j = 0.05$ and the other conditions are the same. We have

$$E = 10,000(0.03) + 10,000 \frac{0.025}{(1.025)^{20} - 1} \quad \text{[Formula (3)]}$$

$$= 300.00 + 10,000(0.03914713) \quad \text{[Table VII]}$$

$$= 300.00 + 391.47 = \$691.47.$$

Example 3. Find the semi-annual expense in Example 1, if the sinking fund is accumulated at $(j = .06, p = 2)$.

Solution. Here, $j = 0.06$ and the other conditions are the same. We have

$$E = 10{,}000(0.03) + 10{,}000\, \frac{0.03}{(1.03)^{20} - 1}$$

$$= 300.00 + 10{,}000(0.03721571)$$

$$= 300.00 + 372.16 = \$672.16.$$

Example 4. Find the semi-annual expense in Example 1, if the sinking fund is accumulated at $(j = .07,\, p = 2)$.

Solution. Here, $j = 0.07$ and the other conditions are the same. We have

$$E = 10{,}000(0.03) + 10{,}000\, \frac{0.035}{(1.035)^{20} - 1}$$

$$= 300.00 + 10{,}000(0.03536108)$$

$$= 300.00 + 353.61 = \$653.61.$$

Compare the answers of Examples 1, 2, 3, and 4. Are the results consistent with the conclusions that we have already drawn?

Exercises

1. A man secures a \$15,000 loan with interest at $6\frac{1}{2}\%$, payable annually. He may take care of the loan (a) by paying the interest as it is due and paying the principal in full at the end of 10 years; or (b) by paying principal and interest in 10 equal annual installments. If a sinking fund can be accumulated at 5%, converted annually, which is the more economical method and by how much?

2. A debt of \$8,000 bears interest at 7%, payable semi-annually, and is due in 7 years. How much should be provided every six months to pay the interest and retire the debt when it is due, if deposits can be accumulated at 6%, converted semi-annually?

3. What would be the semi-annual expense in Exercise 2, if the debt could be retired by paying principal and interest in 14 equal semi-annual installments?

4. A debt of \$20,000 which bears interest at 5%, payable semi-annually, is to be paid in full in 20 years. The debtor has the privilege of paying the principal and interest in 40 equal semi-annual payments, or paying the interest semi-annually and paying the principal in full at the end of 20 years. Compare the two methods if a sinking fund may be created by making semi-annual payments which accumulate at (a) 4%, converted semi-annually; (b) 5%, converted semi-annually; (c) 6%, converted semi-annually.

45. Retirement of a bonded debt.—In the retirement of a debt which has been contracted by issuing bonds of given denominations, the periodic payments cannot be the same, because the payment on principal at the end of each period must be a multiple of the denomination (face value or

par value) of the bonds or their redemption value* (if not redeemed at par). By varying the number of bonds retired each time the payments can be made to differ from each other by an amount not greater than the redemption value of one bond. An example will make the method clear.

Example. Construct a schedule for the retirement, in 8 years, of a $30,000 debt, consisting of bonds of $100 face value, bearing interest at 6% payable annually, by making annual payments as nearly equal as possible.

Solution. If the annual payments were all equal, we would have

$$R = 30,000 \frac{0.06}{1 - (1.06)^{-8}} = \$4,831.08.$$

The interest for the first year is $1,800. Subtracting this amount from $4,831.08 leaves $3,031.08 available for the retirement of bonds. This will retire 30 bonds, for $3,000 is the multiple of $100 which is nearest to $3,031.08. This makes a total payment (for interest and bonds retired) of $4,800 for the first year. Subtracting the $3,000 which has been paid on the principal from $30,000 leaves $27,000 as the principal at the beginning of the second year. The interest on this amount is $1,620, which when subtracted from $4,831.08 leaves $3,211.08 to be used for retiring bonds the second year. This will retire 32 bonds, because $3,200 is the multiple of $100 which is nearest to $3,211.08. Continuing this process, we obtain the following schedule:

Year	Unpaid Principal at Beginning of Year	Interest Due at End of Year	Number of Bonds Retired	Value of Bonds Retired	Annual Payment
1	$30,000.00	$1,800.00	30	$3,000.00	$4,800.00
2	27,000.00	1,620.00	32	3,200.00	4,820.00
3	23,800.00	1,428.00	34	3,400.00	4,828.00
4	20,400.00	1,224.00	36	3,600.00	4,824.00
5	16,800.00	1,008.00	38	3,800.00	4,808.00
6	13,000.00	780.00	41	4,100.00	4,880.00
7	8,900.00	534.00	43	4,300.00	4,834.00
8	4,600.00	276.00	46	4,600.00	4,876.00
Totals	$144,500.00	$8,670.00	300	$30,000.00	$38,670.00

* See Art. 54 for definitions.

As a check on the work of the schedule the interest on the total of the unpaid principals should equal the total of the interest due; and the sum of the totals in the third and fifth columns should equal the total in the sixth column.

We notice that the annual payment each year varies from the computed payment, $4,831.08, by an amount less than $50 (one-half the face of one bond).

.

Exercises

1. Solve the illustrative Example when the bonds have a $500 face value.

2. A city borrows $100,000 to erect a school building. The debt is in the form of bonds of face value $1,000 bearing interest at 5% converted annually. The bonds are to be retired by 10 annual installments as nearly equal as possible. Set up a schedule showing the number of bonds retired each year.

Problems

1. Construct the amortization schedule for the repayment of a loan of $10,000, principal and interest at 5% nominal, payable semi-annually, in ten semi-annual payments.

2. Construct an accumulation schedule for the accumulation of $10,000 in 10 equal semi-annual installments at 6% interest, converted semi-annually.

3. A man deposits in a sinking fund equal quarterly payments sufficient to accumulate to $5,000 in 5 years at 6% converted quarterly. What is the amount in the sinking fund just after the 9th quarterly payment has been made?

4. A debt of $8,000 bearing 5% interest, converted quarterly, is arranged to be paid principal and interest in 30 equal quarterly payments. How much remains unpaid on the principal just after the 17th payment is made?

5. The cash price of a house is $7,000. $2,000 cash is paid and it is arranged to pay the balance by 70 equal monthly payments, including interest at 6%, converted monthly. Just after the 50th payment is made, what is the balance due on the principal?

6. A mortgage for $7,500, bearing 6% interest payable semi-annually, is due in 12 years. A fund to care for the principal when it becomes due is established by making semi-annual payments into a sinking fund. (a) Find the semi-annual expense of the mortgage if the sinking fund accumulates at 5% semi-annually. (b) Find the semi-annual expense of the mortgage if it is amortized by equal semi-annual payments.

7. What is the book value of the debt in Problem 6 at the end of 7 years, (a) if the sinking fund method is used, (b) if the amortization method is used?

8. A man buys a house for $5,500, paying $1,500 cash. The balance with interest at 6% is to be cared for by paying $700 at the end of each year as long as such a payment is necessary and then making a smaller payment at the end of the last year. Find the number of full payments and the amount of the final payment. What amount remains due just after making the 5th payment?

9. A city borrows \$100,000 at 5%. The debt is to be retired in 10 years by the accumulation of a sinking fund that is invested at 4% effective. What is the total annual expense to the city?

10. A county borrows \$50,000 to build a bridge. The debt is to be paid by amortization of the principal in 15 years at 5%. At the end of the tenth year what principal remains outstanding?

11. A fraternity chapter borrows \$60,000 at 6% to build a house. The debt is to be amortized in 25 years. What is the annual payment?

12. A fraternity chapter borrows \$60,000 at 6% to build a house. A sinking fund can be built up at 5%. What amount must be raised annually to pay this debt if the payments are to extend over 30 years?

Review Problems *

1. A well-known finance company requires payments of \$7.27 a month for 18 months for a loan of \$100. What rate of interest does the borrower pay?

2. The cash price of an automobile is \$995. An advertisement of a dealer stated, "If you want to buy on terms, pay a little more for the convenience, \$329 down and \$63 a month for 12 months." What rate of interest does one pay who purchases the car on the installment plan?

3. An automobile, cash price \$1,300, was purchased on the terms, \$507 down and \$57.50 a month for 18 months. What rate of interest was paid?

4. Solve $A = Ra_{\overline{n}|i}(1 + i)^{-m}$ (a) for m; (b) for n.

5. If C is the first cost and D is the renewal cost of an article whose life is r years, show that the capitalized cost, K, at the rate i is given by

$$K = C + \frac{D}{i} \cdot \frac{1}{s_{\overline{r}|i}}.$$

6. A machine costs \$2,500 new and must be replaced at the end of each 10 years. Find the capitalized cost if money is worth 5% and if the old machine has a salvage value of \$500.

7. A debt of \$10,000 with interest at $(j = .06, m = 12)$ is to be amortized by payments of \$100 a month. After how many payments will the debt be paid in full? What is the final partial payment?

8. A \$10,000 bequest invested at 4% is to provide a scholarship of R at the end of each year for 25 years at which time the bequest is to be exhausted. Find R.

9. The Empire State Building was erected at a cost of \$52,000,000. If its estimated useful life is 100 years and its salvage value is to pay for its demolishing, what net annual income for 100 years would yield 5% on the investment?

10. If interest is at 5% for the first 10 years and 4% thereafter, what equal annual payments for 15 years will repay a \$10,000 loan?

11. Show (a) by verbal interpretation and (b) algebraically that

$$A(1 + i)^r = Rs_{\overline{r}|i} + Ra_{\overline{n-r}|i}$$

when $r \leqq n$.

CHAPTER V

DEPRECIATION

46. Definitions.—A building, a machine or any article of value into which capital has been invested will be referred to as an *asset*. These assets decrease in value due to use, action of the elements, lack of care, old age, and other causes. A part of this decrease in value may be taken care of by proper repairs, but repairs will not cause an asset to retain its original value. In fact, some assets will decrease in value whether they are used or not. This may be due to new inventions or decreases in the market prices or a combination of these and other causes. For example, an automobile will decrease in value even though it does not leave the floor of the showroom. (Why?) That part of the decrease in value of an asset which can not be cared for by repairs is commonly known as *depreciation*.

Good business principles demand that capital invested in an asset or a business consisting of several assets, should not be impaired. Hence, from the revenues of the asset or the business there should be set aside, periodically, certain sums, such that the accumulation of these sums at any time plus the value of the asset at that time shall equal its original value. The fund into which these periodical sums are set aside is known as a *depreciation reserve*. This depreciation reserve is usually retained in the business but is carried as a separate item on the books of the business. The object of the accounting for depreciation and the setting aside of a depreciation reserve is to recover only the capital originally invested in the asset. The accountant is not concerned with the replacement of the asset, whether lower or higher than the original cost. His chief concern is that the original capital be not impaired, for this is a fund that must be considered as belonging to the holders of the stock in the business.

These assets may never be replaced at any price for the company may go out of business. Then this accumulated value would be used to retire the capital stock. If the assets are replaced at a lower cost, then only a part of this accumulated value may be considered as used for the replacement. If the assets have to be replaced at a higher cost, then the differ-

ence between this cost and the accumulated value reserve must be met by increasing the original capital. Regardless of the way that depreciation is considered by the accountant, the mathematical principles involved in the treatment of the subject remain the same.

Although an asset may become obsolete or useless for the purpose for which it was intended originally, it may be of value for some other purpose. This value is commonly known as the *scrap value* or *trade in value* of the asset and the time it was in use up to the date it was replaced or discarded is known as its *useful life*. The original value minus the scrap value is defined as the *wearing value* or the *total depreciation* of the asset. At any time during the life of an asset its *book value* may be defined as the original value (or value when it became a part of the business) minus the value of the depreciation reserve. The amount by which the depreciation reserve increases any year is known as the *annual depreciation charge*.

47. Methods of treating depreciation.—There are many methods of treating depreciation. We shall treat four of the most common methods:

(a) The straight line method.
(b) The sinking fund method.
(c) The fixed percentage on decreasing value method.
(d) The unit cost method.

Some of the other methods used are the compound interest method, the service output method, the maintenance method, and so on.

48. The straight line method.—By this method the total depreciation (wearing value) is distributed equally over the life of the asset and the amounts in the depreciation reserve *do not earn interest*. If we let C stand for the original value (cost) of the asset, S stand for its scrap value, n stand for its useful (probable) life, W stand for its wearing value, and D stand for the annual depreciation charge to be made, it follows from the above definition of the straight line method that

$$D = \frac{W}{n}, \tag{1}$$

where $W = C - S$.

Example. A certain asset costs \$2,250. It is assumed that with proper care it will have a scrap value of \$170 after a useful life of 8 years. Using the straight line method, show by schedule and graph the value of the depreciation reserve and the book value of the asset at any time.

Solution.   We have, $C = \$2,250$, $S = \$170$, $n = 8$, and $W = \$2,080$.

Therefore,
$$D = \frac{2,080}{8} = \$260.$$

The value of the depreciation reserve at the end of the first year will be \$260 and this will increase each year by the constant amount, $D = \$260$, until at the end of 8 years it will contain \$2,080. The book value of the asset will decrease each year by the constant amount, $D = \$260$, until at the end of 8 years it will be \$170 (the scrap value).

The following schedule shows the book value of the asset and the amount in the depreciation reserve at any time.

SCHEDULE OF BOOK VALUE AND DEPRECIATION
STRAIGHT LINE METHOD

Age in Years	Book Value	Depreciation Charge	Total in Depreciation Reserve
0	\$2,250.00		
1	1,990.00	\$260.00	\$260.00
2	1,730.00	260.00	520.00
3	1,470.00	260.00	780.00
4	1,210.00	260.00	1,040.00
5	950.00	260.00	1,300.00
6	690.00	260.00	1,560.00
7	430.00	260.00	1,820.00
8	170.00	260.00	2,080.00

Observing the above schedule, we notice that the book value at the end of any year plus the total in the depreciation reserve at that time equals the original cost of the asset.

The changes in the book value and depreciation reserve may also be shown by graphs. [See Fig. 1.]

Observing the graphs for depreciation and book value, we notice that the ordinate for depreciation at any time plus the ordinate for book value at the same time equals the original value of the asset. We also observe that the graphs which represent the book value and depreciation reserve are straight lines. This suggests why this method is known as the straight line method.
Fig. 1.—Graphical Representation of Book Value and Depreciation—
Straight Line Method.

49. Fixed-percentage-on-decreasing-value method.—This method derives its name from the fact that the book value at the end of any year is obtained by decreasing the book value at the end of the preceding year by a fixed percentage. It is assumed that the book value is reduced from the original cost C to the scrap value S at the end of n years, and the amounts in the depreciation reserve do not earn interest.

Let C stand for the original cost of an asset and let x be the fixed percentage by which the book value is decreased each year.

During the first year the decrease in book value is Cx and consequently, the book value at the end of the first year is

$$C_1 = C - Cx = C(1 - x).$$

The book value at the end of the second year is

$$C_2 = C_1(1 - x) = C(1 - x)(1 - x) = C(1 - x)^2.$$

The book value at the end of the third year is

$$C_3 = C_2(1 - x) = C(1 - x)^2(1 - x) = C(1 - x)^3.$$

Continuing our reasoning we find the book value at the end of n years to be

$$C_n = C(1 - x)^n.$$

But the book value of the asset at the end of its useful life, n years, equals its scrap value S. Hence, we have*

$$C (1 - x)^n = S \tag{2}$$

or
$$\log (1 - x) = \frac{\log S - \log C}{n}. \tag{3}$$

Using (3), the fixed percentage may be computed for any particular case.

If we let C_k represent the book value of the asset at the end of k years, we observe that

$$C_k = C(1 - x)^k, \tag{4}$$

and
$$\log C_k = \log C + k \log (1 - x) \tag{5}$$

We further observe that by using (3) and (5) and allowing k to assume all consecutive integers from 1 to n inclusive, we may compute, entirely by the use of logarithms, the successive book values of the asset. An example will illustrate the method.

Example. Find by the fixed percentage method the book values at the end of each year for a machine costing \$800, and having an estimated life of 8 years and a scrap value of \$80. Construct a schedule showing the book values and amount in the depreciation reserve at the end of each year.

Solution. Here, $C = \$800$, $S = \$80$, $n = 8$.
Using (3), we get

$$\log (1 - x) = \frac{\log 80 - \log 800}{8} = 9.87500 - 10.$$

Then using (5), we have

$$\log C_k = \log 800 + k(9.87500 - 10).$$

$$= 2.90309 + k(9.87500 - 10).$$

---

* It will be observed from (2) that, when $S = 0$, we have $x = 1$ for any assigned value of n. That is, the book value is reduced to zero at the end of 1 year, no matter what is the estimated value of n. This means that the method is impractical when S is zero. Even if the ratio of S to C is small, the depreciation charge is likely to be unreasonably large during the first years of operation.

Giving k all values from 1 to 8, we get

$$\log C_1 = 2.77809, \qquad C_1 = \$599.91.$$
$$\log C_2 = 2.65309, \qquad C_2 = 449.87.$$
$$\log C_3 = 2.52809, \qquad C_3 = 337.35.$$
$$\log C_4 = 2.40309, \qquad C_4 = 252.98.$$
$$\log C_5 = 2.27809, \qquad C_5 = 189.71.$$
$$\log C_6 = 2.15309, \qquad C_6 = 142.26.$$
$$\log C_7 = 2.02809, \qquad C_7 = 106.68.$$
$$\log C_8 = 1.90309, \qquad C_8 = 80.00.$$

The student will observe that the actual value of x (fixed percentage) was not needed in the above computations. Should we desire the value of x, we find that $1 - x$ is the antilogarithm of $9.87500 - 10$, or 0.7499. Hence, $x = 0.2501 = 25.01\%$.

Since the book value at the end of the first year is $599.91, the depreciation charge for that year is

$$\$800.00 - \$599.91 = \$200.09.$$

The depreciation charge for the second year is

$$\$599.91 - \$449.87 = \$150.04$$

and the total in the depreciation reserve at the end of two years is

$$\$200.09 + \$150.04 = \$350.13.$$

The following schedule shows the book values and the amount in the depreciation reserve at the end of each year.

SCHEDULE OF BOOK VALUE AND DEPRECIATION
FIXED PERCENTAGE METHOD

Age in Years	Annual Depreciation	Total in Depreciation Reserve	Book Value
0	. . . . . .	. . . . . .	$800.00
1	$200.09	$200.09	599.91
2	150.04	350.13	449.87
3	112.52	462.65	337.35
4	84.37	547.02	252.98
5	63.27	610.29	189.71
6	47.45	657.74	142.26
7	35.58	693.32	106.68
8	26.68	720.00	80.00

The changes in the book value and depreciation reserve may also be shown by graphs.
Fig. 2.—Graphical Representation of Book Value and Depreciation—
Fixed Percentage Method.

50. The sinking fund method.—In the sinking fund method the total depreciation (wearing value) of the asset is provided for by accumulating a sinking fund at a given rate of compound interest. The annual payment into the sinking fund is the payment on an annuity which will have an amount equal to the total depreciation (wearing value) of the asset at the end of its useful life.

If C is the cost, S the scrap value, W the wearing value, and n the estimated useful life of the asset, we find, using $A11$, Art. 31, the annual payment into the sinking fund to be

$$R = W \frac{i}{(1 + i)^n - 1} = \frac{W}{s_{\overline{n}|i}}, \qquad (6)$$

where $W = C - S$.

By this method the depreciation charge for the first year is R and the amount in the depreciation reserve at the end of the first year is R. However, the depreciation charge increases each year and for any subsequent year it is R plus the interest on the amount in the depreciation reserve during that year.

Example. Assuming money worth $4\frac{1}{2}\%$, apply the sinking fund method to the Example discussed in Art. 49.

Solution. Here, $C = \$800$, $S = 80$, $n = 8$, $i = 0.045$, and $W = C - S = \$720$.

Using (6), we get

$$R = 720\frac{0.045}{(1.045)^8 - 1} = \$76.76.$$

The depreciation charge for the first year is $R = \$76.76$. Consequently, the amount in the depreciation reserve at the end of the first year is $\$76.76$ and the book value of the asset at that time is $\$800.00$ less $\$76.76$ or $\$723.24$. The depreciation charge for the second year is R, ($\$76.76$), plus the interest on $\$76.76$ (the amount in the depreciation reserve during the second year) at $4\frac{1}{2}\%$. Thus, the depreciation charge for the second year is $\$76.76 + \$3.45 = \$80.21$. Then, the amount in the depreciation reserve at the end of two years is $\$76.76$ plus $\$80.21$ or $\$156.97$ and the book value of the asset at that time is $\$643.03$. Values for subsequent years are found in a similar manner.

The following schedule will show the values for each year.

SCHEDULE OF BOOK VALUE AND DEPRECIATION
SINKING FUND METHOD

Age in Years	Annual Payment	Interest on Fund	Annual Depreciation Charge	Amount in Depreciation Reserve	Book Value of Asset
0	......	......	......	......	$800.00
1	$76.76	$0.00	$76.76	$76.76	723.24
2	76.76	3.45	80.21	156.97	643.03
3	76.76	7.06	83.82	240.79	559.21
4	76.76	10.84	87.60	328.39	471.61
5	76.76	14.78	91.54	419.93	380.07
6	76.76	18.90	95.66	515.59	284.41
7	76.76	23.20	99.96	615.55	184.45
8	76.76	27.70	104.46	720.01	79.99

The above information is shown by means of graphs in Fig. 3.
Fig. 3.—Graphical Representation of Book Value and Depreciation—
Sinking Fund Method.

51. The unit cost method.—None of the three methods of depreciation already discussed takes into consideration the question of improvements in machinery. The unit cost method is based upon the principle that the value of the old machine should be decreased from year to year to such an extent that the net cost of a unit of output of the machine should be the same as the net cost of a unit of output of a new machine with which it could be replaced. The old machine should be so valued that its unit cost of production, after taking into account all charges for depreciation, repairs, interest, and operating expenses, is the same as that of a new machine. Let us illustrate by an example.

Example 1. Consider the replacement of a machine which costs $300 a year to operate, costs $100 a year for repairs, turns out 25 units of work per year and has a probable life of 5 years. A new machine costs $2,500, costs $400 a year to operate, costs $100 a year for repairs, turns out 40 units of work per year, and has a probable life of 9 years. Find the value of the old machine, assuming money worth 4%.

Solution. Let x be the value of the old machine. The cost of repairs and operation on the old machine is $400. $0.04x$ is the interest on the investment, and

$$x \frac{0.04}{(1.04)^5 - 1}$$

is the annual payment required to accumulate the value of the old machine in 5 years.

$$0.04x + x\,\frac{0.04}{(1.04)^5 - 1} = 0.22462711x.$$

Hence, the unit cost of production for the old machine is

$$\frac{400 + 0.22462711x}{25} = 16 + 0.0089851x.$$

Reasoning the same as above, we find the yearly cost for operating the new machine to be

$$400 + 100 + 2{,}500(0.04) + 2{,}500\,\frac{0.04}{(1.04)^9 - 1} = 836.232475.$$

Hence, the unit cost of production for the new machine is

$$\frac{836.232475}{40} = 20.905812.$$

According to the principle of the unit cost method, we have

$$16 + 0.0089851x = 20.905812,$$

and
$$x = \frac{4.905812}{0.008985} = \$546.00.$$

Hence, assuming money worth 4%, the value of the old machine as compared with the value of the new is $546.00.

We shall now derive a formula for determining the value of the old machine as compared with the new machine. Let

C = the original cost of the new machine,
N = the estimated lifetime of the new machine,
O = the annual operating expense of the new machine not including repairs,
R = the annual cost of repairs for the new machine,
$K =$ the annual rent of an annuity required to accumulate C in N years,
U = the number of units of output per year.

Let the corresponding letters o, r, k, and u denote the corresponding quantities for the old machine. Let c be the value of the old machine at

the time of making the comparison, and n the remaining lifetime of the old machine.   Let i be the rate of interest.

The unit cost for the new machine is

$$\frac{O + R + K + Ci}{U}$$

and the unit cost of the old machine is

$$\frac{o + r + k + ci}{u}.$$

According to the principle of the unit cost method, we have

$$\frac{O + R + K + Ci}{U} = \frac{o + r + k + ci}{u}. \tag{7}$$

Since,
$$K = \frac{C}{s_{\overline{N}|}} \quad \text{and} \quad k = \frac{c}{s_{\overline{n}|}},$$

$$K + Ci = C\left(i + \frac{1}{s_{\overline{N}|}}\right) = \frac{C}{a_{\overline{N}|}} \qquad [(14), \text{Art. } 26]$$

and
$$k + ci = c\left(i + \frac{1}{s_{\overline{n}|}}\right) = \frac{c}{a_{\overline{n}|}}.$$

Then (7) becomes

$$\frac{O + R + \dfrac{C}{a_{\overline{N}|}}}{U} = \frac{o + r + \dfrac{c}{a_{\overline{n}|}}}{u}. \tag{8}$$

Solving (8) for c, we have

$$c = ua_{\overline{n}|}\left[\frac{O + R + \dfrac{C}{a_{\overline{N}|}}}{U} - \frac{o + r}{u}\right]. \tag{9}$$

If the number of units of output of the old and new machines are the same, $U = u$, (9) reduces to

$$c = a_{\overline{n}|}\left[O + R + \frac{C}{a_{\overline{N}|}} - o - r\right]. \tag{10}$$

If $O = o$, along with $U = u$, (10) reduces to

$$c = a_{\overline{n}|}\left(R + \frac{C}{a_{\overline{N}|}} - r\right). \tag{11}$$

If $O + R = o + r$, then (10) becomes

$$c = \frac{Ca_{\overline{n}|}}{a_{\overline{N}|}}. \tag{12}$$

Example 2. A machine having a remaining service life of 6 years turns out 30 units of work per year. Its operation costs $300 per year, and repairs cost $225 per year. A new machine, that turns out 40 units of work, costs $1,000. It has a probable life of 10 years and will cost $350 a year for operation and $250 a year for repairs. Assuming money worth 5%, find the value of the old machine.

Solution. Here, $C = \$1,000$, $N = 10$, $O = \$350$, $R = \$250$, $U = 40$, $n = 6$, $o = \$300$, $r = \$225$, and $u = 30$.

$$\frac{1}{a_{\overline{N}|}} = \frac{1}{a_{\overline{10}|}} = 0.12950458,$$

$$a_{\overline{n}|} = a_{\overline{6}|} = 5.07569206.$$

Substituting in (9), we have

$$c = 30(5.07569206) \left[\frac{350 + 250 + 1,000(0.12950458)}{40} - \frac{300 + 225}{30} \right]$$

$$= 30(5.07569206) [18.23761 - 17.50000]$$

$$= 152.2708(0.7376) = \$112.31.$$

Exercises

1. A farmer pays $235 for a binder. The best estimates show that it will have a life of 8 years and a scrap value of $15. Find the annual depreciation charge by the straight line method and construct a schedule of depreciation.

2. A tractor costs $1,200. It is estimated that with proper care it will have a life of 8 years with a scrap value of $50 at the end of this time. Construct a depreciation schedule, using the sinking fund method and assuming 4% interest.

3. An automobile, costing $950, has an estimated life of 5 years and a scrap value of $50. Prepare a depreciation schedule using the fixed percentage method.

4. A machine costs $5,000. The best estimates show that after 10 years of use its scrap value will be $1,000. (a) Making use of the fixed percentage method, find the

book value of the machine at the ends of **7** and **8** years, respectively. (b) What is the depreciation charge for the 8th year?

5. Solve Exercise 4, making use of the sinking fund method and assuming an interest rate of 5%.

6. Solve Example 2 of Art. 51, if the new machine could turn out 45 units of work per year. Interpret the results.

7. How many units of work must be turned out by the new machine of Example 2, Art. 51, so that the old machine would not have any value?

8. From formula (9) derive a formula for the number of units a new machine should turn out in order to make the old machine worthless.

9. A machine having a probable life of 18 years has been in use for 8 years and turns out 200 units of work each year. The cost for operating is $600 per year and repairs are $400 per year. A new machine costs $3,000 and has a probable life of 20 years and will turn out 200 units of work per year. It would cost $500 per year to operate this machine and repairs would cost $300 per year. Neither machine is supposed to have any salvage value. What is the value of the old machine on a 6% interest basis?

10. What output for the new machine in Exercise 9 would render the value of the old machine zero?

11. An asset costs $1,000. It is estimated that with proper care it can be used for 8 years at which time it will have a value of $50. Using the sinking fund method and assuming 4% interest, find the wearing value that remains at the end of 5 years. [Hint: The wearing value that remains at the end of any year equals the total wearing value minus the amount in the depreciation reserve at that time. Observing the schedule for the Example of Art. 50, we see that the wearing value that remains after 5 years of use is ($720.00 − $419.93) = $300.07].

12. Solve Exercise 11, making use of the fixed percentage method.

13. Solve Exercise 11, making use of the straight line method.

52. Depreciation of mining property.—Investment in mines, oil wells, and timber tracts should yield not only interest on the investment, but additional income to provide for the restoration of the original capital when the asset is exhausted. The mining engineer can estimate the net annual return on the mine and the number of years before the mineral will be exhausted. From this net annual return, interest on the capital invested must be taken and also an annual payment to a depreciation reserve which shall accumulate to the original cost of the mine, less the salvage value, by the time it is exhausted.

An important problem in connection with mining property is, having given the net annual yield and the number of years this yield will continue, to determine the price that should be paid for the mines so that this net annual yield will provide a sufficient rate of interest on the investment and an annual payment to the depreciation reserve.

Assume that R is the net annual return and that this yield will continue for n years. Also assume that the rate of yield on the invested capital is to be r and the depreciation reserve is to be accumulated at rate i.

If we let P stand for the purchase price of the property, then the annual return on the capital invested would be Pr. Hence, the amount left from the net annual return, for the annual contribution to the depreciation reserve, would be $(R - Pr)$, and this must accumulate to $P - S$ in n years at rate i, where S is the salvage value.

Therefore, we have

$$P - S = (R - Pr) \frac{(1 + i)^n - 1}{i} = (R - Pr)s_{\overline{n}|i}. \tag{12'}$$

When $S = 0$,

$$P = \frac{R}{r + \dfrac{i}{(1 + i)^n - 1}} = \frac{R}{r + \dfrac{1}{s_{\overline{n}|i}}}. \tag{13}$$

Example. A mining engineer estimates that a copper mine will yield a net annual income of $50,000 for the next 20 years. What price should be paid for the mine, if the depreciation reserve is to accumulate at 5%, if 10% is to be realized on the capital invested, and if $S = 0$?

Solution. We have, $R = \$50,000$, $n = 20$, $r = 10\%$, and $i = 5\%$. Making use of (13), we get

$$P = \frac{50,000}{0.10 + \dfrac{0.05}{(1.05)^{20} - 1}} = \frac{50,000}{0.10 + \dfrac{1}{s_{\overline{20}|.05}}}$$

$$= \frac{50,000.00}{0.10 + (0.03024259)} = \frac{50,000.00}{0.13024259}$$

$$= \$383,899, \text{ purchase price.}$$

This would give a return of $38,389.90 on the invested capital and leave $50,000 - \$38,389.90 = \$11,610.10$ for the annual payment into the depreciation reserve. This annuity in 20 years at 5% will amount to $383,899.

Exercises

1. An oil well which is yielding a net annual income of $30,000 is for sale. The geologist estimates that this annual income will continue 10 years longer. What should be paid for the well, if the depreciation reserve is to accumulate at 4½%, and 8% is to be realized on the invested capital?

2. A gold mine is yielding a net annual income of $100,000. Careful estimates show that the mine will continue to yield this net annual income for 25 years longer, at which time it will be exhausted. Find its value, if a return of 9% on the invested capital is desired and the depreciation reserve accumulates at 5%.

3. A 1,000 acre tract of timber land is for sale. It is estimated that the net annual income from the timber will be $125,000 for the next 5 years, at which time the land will be worth $25 per acre. How much per acre should be paid for the land, if the purchaser desires 10% on his investment and the depreciation reserve can be accumulated at 5%?

4. $750,000 is paid for a mine which will be exhausted at the end of 25 years. What net annual income is required from the mine, if 8% is to be realized on the investment after the annual payments have been made into the depreciation reserve which accumulates at 4%?

53. Composite life of a plant.—We will consider that a manufacturing plant consists of several parts, each having a different probable life. By the composite life of a plant we mean a sort of average lifetime of the several parts, and we may define it more precisely as the *time required for the total of the equal annual payments to the depreciation reserves of the several parts to accumulate to the total wearing value of the plant.*

Let $W_1, W_2, W_3, \cdots, W_r$ be the wearing values of the several parts, with probable lives of $n_1, n_2, n_3, \cdots, n_r$ respectively, and let $W = W_1 + W_2 + W_3 + \cdots + W_r$ be the wearing value of the entire plant. Also let $D_1, D_2, D_3, \cdots, D_r$ be the annual payments to the depreciation reserves for the several parts and let $D = D_1 + D_2 + D_3 + \cdots + D_r$ be the depreciation for the whole plant.

Then by the straight line method, we have

$$n = \frac{W}{D} = \frac{W_1 + W_2 + W_3 + \cdots + W_r}{D_1 + D_2 + D_3 + \cdots + D_r},$$

or

$$n = \frac{W_1 + W_2 + W_3 + \cdots + W_r}{\dfrac{W_1}{n_1} + \dfrac{W_2}{n_2} + \dfrac{W_3}{n_3} + \cdots + \dfrac{W_r}{n_r}}. \tag{14}$$

Example 1. A plant consists of parts A, B, and C, having the following values, scrap values, and probable lives, respectively:

A	$25,000	$5,000	20 years
B	20,000	2,000	18 years
C	8,000	1,000	14 years

Find its composite life.

Solution. Here, $W_1 = \$20,000$, $W_2 = \$18,000$, $W_3 = \$7,000$, $n_1 = 20$, $n_2 = 18$, $n_3 = 14$. Using (14), we get

$$n = \frac{20,000 + 18,000 + 7,000}{\dfrac{20,000}{20} + \dfrac{18,000}{18} + \dfrac{7,000}{14}}$$

$$= \frac{45,000}{2,500} = 18.$$

Hence, the composite life is 18 years.

If the sinking fund method is used, we have

$$(D_1 + D_2 + \cdots + D_r)\, s_{\overline{n}|i} = (W_1 + W_2 + \cdots + W_r),$$

or
$$D\, s_{\overline{n}|i} = W, \tag{14'}$$

where $D_1 = W_1 \dfrac{1}{s_{\overline{n_1}|i}}$, and so on.

Solving (14') for n by the use of logarithms, we get

$$n = \frac{\log\,(Wi + D) - \log D}{\log\,(1 + i)}. \tag{15}$$

The value for n obtained from (15) gives us the composite life. We may also express (14') in the form

$$s_{\overline{n}|i} = \frac{(1 + i)^n - 1}{i} = \frac{W}{D}, \tag{16}$$

and read the approximate value for n from Table V.

Example 2. Solve Example 1, using the sinking fund method and 5% interest.

Solution. Here, $W_1 = \$20,000$, $W_2 = \$18,000$, $W_3 = \$7,000$, $n_1 = 20$, $n_2 = 18$, $n_3 = 14$, $i = 0.05$.

Whence,
$$D_1 = 20,000\, \frac{1}{s_{\overline{20}|.05}} = \$604.85,$$

$$D_2 = 18,000\, \frac{1}{s_{\overline{18}|.05}} = \$639.83,$$

$$D_3 = 7,000\, \frac{1}{s_{\overline{14}|.05}} = \$357.17,$$

$$D = \$1,601.85 \quad \text{and} \quad W = \$45,000.$$

Using (16), we get

$$s_{\overline{n}|.05} = \frac{(1.05)^n - 1}{0.05} = \frac{45,000}{1,601.85} = 28.0925.$$

From Table V, we notice that the nearest value of n is 18. In fact, when $n = 17$, the table value is 25.8404, and when $n = 18$, the table value is 28.1324. Hence, n is a little less than 18 and we say the composite life is approximately 18 years.

Using (15), we have

$$n = \frac{\log\,(3,851.85)\,-\,\log\,(1,601.85)}{\log\,(1.05)}$$

$$= \frac{3.58567 - 3.20462}{0.02119} = \frac{0.38105}{0.02119}$$

$$= 17.98, \text{ or approximately } 18.$$

Exercises

1. Allowing interest at 5%, find the composite life of the plant consisting of the following parts.

Parts	Original Cost	Scrap Value	Life
Building......	$150,000	$40,000	25 years
Machinery....	75,000	25,000	25 years
Patterns....	15,000	......	10 years
Tools........	25,000	5,000	12 years

2. Solve Exercise 1, using the straight line method.

3. Allowing interest at 4%, find the composite life of the plant consisting of the following parts.

Parts	Cost	Scrap Value	Life
A	$200,000	$30,000	50 years
B	150,000	20,000	40 years
C	50,000	10,000	35 years
D	30,000	5,000	20 years
E	25,000	5,000	25 years

4. Solve Exercise 3 by the straight line method.

Problems

1. A church with a probable life of 75 years has just been completed at a cost of $125,000. It is free of debt. For its replacement at the end of its probable life the congregation plans to make annual payments from their current funds into a sinking fund that will earn 4% effective. What is the annual payment?

2. The value of a machine decreases at a constant annual rate from the cost of $1,200 to the scrap value of $300 in 6 years. Find the annual rate of decrease, and the value of the machine at the ends of one, two, and three years.

3. The United States gross imports of crude rubber increased from 252,922 long tons in 1920 to 563,812 long tons in 1929. Find the annual rate of increase during this period, assuming that the annual rate of increase was constant.

4. A dormitory is planned at a cost of $250,000. Its probable life is estimated to be 50 years at the end of which time its scrap value will be zero. To reconstruct the building at the end of its probable life, a sinking fund, into which semi-annual payments will be made, is to be created, the fund earning interest at $(j = .04, m = 2)$. What is the semi-annual payment?

5. It is estimated that a quarry will yield $15,000 per year for 8 years, at the end of which time it will be worthless. If a probable purchaser desires 8% on his investment and is able to accumulate a redemption fund at 4%, what should he pay for the quarry?

6. On a 3% basis find the annual charge for replacement of a plant, and its composite life, if the several parts are described by the table:

Part	Life in years	Cost	Scrap Value
A	40	$200,000	$10,000
B	25	50,000	3,000
C	15	20,000	1,000
D	10	10,000	1,000

7. A philanthropist wishes to donate a building to cost $200,000 and to provide for its rebuilding every 50 years at the same cost. He also wishes to provide for its complete renovation every 10 years at a cost of $20,000 and for annual repairs at a cost of $2,000. What amount should he donate, if the sums can be invested at 4%?

8. In starting a transfer business it is planned to purchase 10 cabs annually for 5 years at a cost of $1,000 per cab. On a 4% basis, what is the present value of these purchases if the first allotment is purchased immediately?

It is estimated that 5 years is the service life of these cabs. It is also planned to replace the worn out cabs by making annual payments at the end of each year into a sinking fund that earns 4% effective, R at the end of the first year, $2R$ at the end of the second year, $3R$ at the end of the third year, $4R$ at the end of the fourth year, $5R$ at the end of the fifth and later years. What is the annual payment into the sinking fund at the end of the first year? at the end of the second year? at the end of the fifth year? What is the amount in the sinking fund just after the first allotment for replacements? (See Art. 38.)

9. In starting a transfer business it is planned to purchase 10 cabs immediately, 8 cabs at the beginning of the second year, 6 at the beginning of the third year, 4 at the beginning of the fourth year and 2 at the beginning of the fifth year. On a 4% basis, what is the present value of these purchases if each cab costs $1,000? (See Art. 38.)

10. Find the present value of the output of an oil well on the assumption that it will produce a net return of $25,000 the first year, diminishing each year by $5,000 until it is exhausted at the end of the fifth year. Use interest at 8% effective.

11. Show that the unit cost plan of appraisal of value gives the same result as the sinking fund method when the new and the old machines have the same output and the same annual expense charge for operation and upkeep.

Review Problems *

1. A quarry has sufficient stone to yield an income of $20,000 a year for 5 years at the end of which time it will be exhausted. Find the value of the quarry if the investment is to yield 8% and the redemption fund is accumulated at 4%.

2. Telephone poles set in soil last 12 years, in concrete 20 years. If a telephone pole set in soil costs $6, what can the company afford to pay to set the pole in concrete if money can be invested at 4%?

3. In computing the annual return at rate i on the capitalized cost, K, of an article, show that the return would be equivalent to allowing interest on the original investment, C, and allowing for depreciation by (6) Art. 50. (See Problem 5, page 121.)

4. A city incurs a debt of $200,000 in constructing a high-school building. Which would be better: to pay the debt, principal and interest at $6\frac{1}{2}\%$ in 20 annual installments, or to pay 6% interest each year on the debt and pay a fixed amount annually for 20 years into a sinking fund which accumulates at 4%?

5. A county borrows $75,000 to build a bridge. The debt is to be paid by the amortization of the principal in 15 years at 6%. At the end of the tenth year what part of the debt is unpaid?

6. A man pays $1,000 a year for 4 years and $2,000 a year for four years on a debt of $10,000 bearing interest at 6%. What part of the debt is unpaid at the end of 8 years?

7. A machine costing $5,000 has an estimated life of 10 years and a scrap value of $500. Find the constant rate at which it depreciates. What is its value at the end of the second year?

8. If W_r is the wearing value of a machine at the end of r years by the sinking fund method, show that

$$W_r = W \cdot \frac{a_{\overline{n-r}|}}{a_{\overline{n}|}}.$$

* For additional review problems, see end of this book.

CHAPTER VI

VALUATION OF BONDS

54. Definitions.—A *bond* may be defined as a certificate of ownership in a portion of a debt due from a city, corporation, government, or an individual. It is a promise to pay a stipulated sum on a given date, and to pay interest or *dividends* at a specified *dividend rate* and at definite intervals. The interval between dividend payments is usually a year, a half year, or a quarter year. The amount named in the bond is called the *face value* or *par value*. When the sum due is repaid as specified in the bond, the bond is surrendered to the debtor and it is said to be redeemed. The price at which a bond is redeemed is called the *redemption price*. It may be redeemed *at par, below par* or *above par*. When the redemption price of a bond is the same as the face value, it is said to be redeemed *at par*; if it is more than its face value it is said to be redeemed *at a premium*; and if it is less than its face value it is said to be redeemed *at a discount*.

55. Purchase price.—Bonds are usually bought to yield the purchaser a certain rate of interest on his investment. This rate may be very different from the rate of interest specified in the bond. To avoid confusion, we shall designate the rate of interest specified in the bond as the *dividend rate* and the rate of interest received by the purchaser, on his investment, as the *investment rate*. When an individual buys a bond he expects to receive the periodic dividends as they fall due from the date of purchase to the redemption date and also receive the redemption price when due. *It is clear then that the purchase price is really equal to the present value of the redemption price plus the present value of the annuity made from the periodic dividends, both figured at the investment rate.*

Example 1. Find the purchase price of a $1,000, 4¼% bond, dividends payable annually, to be redeemed at par in 18 years when the investment rate is to be 6% annually.

Solution. Here, the redemption price is \$1,000, the dividend is \$42.50 annually. Denoting the purchase price by P, we get

$$P = 1,000(1.06)^{-18} + 42.50\,\frac{1 - (1.06)^{-18}}{0.06}$$

$$= 1,000(0.3503438) + 42.50(10.8276035)$$

$$= 350.34 + 460.17 = \$810.51.$$

Example 2. Find the purchase price of the above bond if it is to be redeemed at \$950.

Solution. $P = 950(1.06)^{-18} + 42.50\,\dfrac{1 - (1.06)^{-18}}{0.06}$

$$= 332.83 + 460.17 = \$793.00$$

If we let $\quad C =$ the redemption price,

$\qquad (j, m) =$ nominal investment rate,

$\qquad\quad n =$ number of years before redemption,

$\qquad\quad R =$ the annual rent of the dividends,

$\qquad\quad p =$ the number of dividend payments each year,

and $\qquad\quad P =$ the purchase price,

we may write down the following general formula which will give the purchase price under all conditions.

$$P = C\left(1 + \frac{j}{m}\right)^{-mn} + R\,\frac{1 - \left(1 + \dfrac{j}{m}\right)^{-mn}}{p\left[\left(1 + \dfrac{j}{m}\right)^{m/p} - 1\right]}. \tag{1}$$

Now, if $m = p$ (that is, if the interest is converted at the same time that the dividends are paid), the above formula reduces to

$$P = C\left(1 + \frac{j}{p}\right)^{-np} + \frac{R}{p}\,\frac{1 - \left(1 + \dfrac{j}{p}\right)^{-np}}{\dfrac{j}{p}}. \tag{2}$$

In most cases formula (2) will apply.

When P is greater than C, the bond is *bought at a premium*. The difference, $(P - C)$, is the *premium*. Similarly, when P is less than C, the bond is *bought at a discount*. The difference, $(C - P)$, is the *discount*. When P equals C the bond is *bought at par*. The bond in Example 1 was bought at a discount of ($1,000 - $810.51), or $189.49.

Example 3. Find the purchase price of a $500, 6% bond, dividends payable semi-annually, to be redeemed at par in 20 years, when the investment rate is to be $5\frac{1}{2}$% converted semi-annually.

Solution. Here, $C = $500, $n = 20$, $j = 5\frac{1}{2}$%, $R = $30, $m = p = 2$. Using formula (2), we have

$$P = 500(1.0275)^{-40} + 15\frac{1 - (1.0275)^{-40}}{0.0275}$$

$$= 500(0.33785222) + 15(24.07810106)$$

$$= 168.926 + 361.172 = $530.10$$

$$\text{Premium} = $530.10 - $500$$

$$= $30.10.$$

Example 4. A $500, 5% bond, dividends payable semi-annually, is to be redeemed in 15 years at 104 (at 104% of the face). What should its purchase price be, if the investment rate is to be 6% converted semi-annually?

Solution. Since the bond is to be redeemed at 104, we have $C = $520. $n = 15$, $j = 6$%, $R = $25, $m = p = 2$.
Making use of (2), we find

$$P = 520(1.03)^{-30} + 12.50\frac{1 - (1.03)^{-30}}{0.03}$$

$$= 520(0.41198676) + 12.50(19.60044135)$$

$$= 214.233 + 245.006 = $459.24.$$

$$\text{Discount} = $520 - $459.24 \quad = $60.76$$

If we let K equal the present value of the redemption price $= C\left(1 + \dfrac{j}{p}\right)^{-np}$, and g equal the ratio of the annual rent of the dividends to the redemption price $= \dfrac{R}{C}$, formula (2) reduces to

$$P = K + \frac{g}{j}(C - K). \tag{3}$$

The student will notice that (3) does not require an annuity table for its evaluation. It was first established by Makeham, an English actuary.

CAUTION. Formula (2) was derived under the assumption $m = p$. Formula (3) was derived from (2). Therefore, (3) may be used only when $m = p$.

Exercises

Find the purchase price of each of the following:

1. A \$500, 6% bond, dividends payable semi-annually, redeemable in 10 years at par, the investment rate to be 5% convertible semi-annually.

2. A \$1,000, 5% bond, dividends payable semi-annually, redeemable in 12 years at 105, the investment rate to be 6% convertible semi-annually.

3. A \$10,000, 4% bond, dividends payable quarterly, redeemable in 20 years at 110, the investment rate to be 5% convertible quarterly.

4. A \$5,000, 7% bond, dividends payable annually, redeemable in 18 years at par, the investment rate to be 6% convertible annually.

5. A \$500, 5½% bond, dividends payable semi-annually, redeemable in 14 years at 102, the investment rate to be 6% convertible semi-annually.

6. Establish formula (3).

7. Use formula (3) to solve Example 3.

8. A \$2,000, 5% bond, dividends payable semi-annually, will be redeemed at 105 at the end of 10 years. Find the purchase price to yield 7% converted semi-annually.

9. Solve Exercise 8, with the yield rate (investment rate) 7% converted annually.

10. Should an investor, who wishes to make 6% (converted semi-annually) or more on his money, buy bonds at 88 which are to be redeemed in 10 years and bear 5% dividends payable semi-annually?

11. A \$5,000, 6% bond, dividends payable semi-annually, is to be redeemed in 16 years at 106. What should be paid for the bond if 5% (convertible annually) is to be realized on the investment?

56. Premium and discount.—If we subtract C from both members of formula (3) we will obtain the excess of purchase price over the redemption price. This result may be positive, negative, or zero. That is, the purchase price may be greater than the redemption price, less than the redemption price, or equal to the redemption price.

We have, if E is the excess,

$$E = P - C = K + \frac{g}{j}(C - K) - C$$

$$= \frac{g - j}{j}(C - K)$$

$$= \frac{g - j}{j}\left[C - C\left(1 + \frac{j}{p}\right)^{-np}\right]$$

$$= C\frac{g - j}{p} \cdot \frac{1 - \left(1 + \frac{j}{p}\right)^{-np}}{\frac{j}{p}}.$$

If we let k equal the excess of purchase price per unit of redemption price, it follows from the above equation that

$$k = \frac{g - j}{p} \cdot \frac{1 - \left(1 + \frac{j}{p}\right)^{-np}}{\frac{j}{p}}, \tag{4}$$

$$E = P - C = Ck, \quad \text{and} \quad P = C + Ck. \tag{5}$$

Example 1. A \$1,000, 6% semi-annual bond is to be redeemed in 10 years at \$1,050. Find the purchase price if the investment is to yield 5% semi-annually.

Solution. Here, $C = \$1,050$, $n = 10$, $j = 0.05$, $m = p = 2$, and $g = \frac{60}{1,050} = 0.057143$. Substituting in (4), we have

$$k = \frac{0.057143 - 0.05}{2} \cdot \frac{1 - (1.025)^{-20}}{0.025}$$

$$= (0.003571)(15.58916229)$$

$$= 0.055669.$$

And from (5), we get

$$E = P - C = 1,050(0.055669) = \$58.45.$$

Hence, the purchase price is \$58.45 more than the redemption price and

$$P = \$1,050 + \$58.45 = \$1,108.45.$$

In actual practice bonds are usually redeemed at par. Then C becomes the face value and $g = \dfrac{R}{C}$ becomes the actual dividend rate. Also, the value, k, obtained from (4) is the excess of purchase price per unit of face value, and the value, $P - C$, obtained from (5) is the premium or discount at which the bond is purchased. In fact, k is the premium or discount per unit of face value. It is evident that k is a premium when

$$g > j;$$

is a discount when

$$g < j;$$

is at par when

$$g = j.$$

Example 2. Solve Example 1, if the bond is to be redeemed at par.

Solution. Here, $C = \$1,000$, $n = 10$, $m = p = 2$, $j = 0.05$, and $g = 0.06$. We have

$$k = \frac{0.06 - 0.05}{2} \cdot \frac{1 - (1.025)^{-20}}{0.025} \quad \text{[Formula (4)]}$$

$$= (0.005)(15.58916229)$$

$$= 0.0779458.$$

And $\quad E = P - C = 1,000(0.0779458) = \$77.95$

$$= \text{the premium.}$$

Hence, $\qquad P = \$1,000 + \$77.95 = \$1,077.95.$

Example 3. A $500, 5% semi-annual bond is to be redeemed in 15 years at par. Find the purchase price if the investment is to yield $5\frac{1}{2}\%$ semi-annually.

Solution. Here, $C = \$500$, $n = 15$, $m = p = 2$, $j = 0.055$, and $g = 0.05$. We have

$$k = \frac{0.05 - 0.055}{2} \cdot \frac{1 - (1.0275)^{-30}}{0.0275} \quad \text{[Formula (4)]}$$

$$= - (0.0025)(20.24930130) = - 0.0506233.$$

And $\quad E = P - C = 500(-0.0506233) = - \$25.31$

Hence, $\qquad P = \$500 - \$25.31 \quad = \$474.69.$

That is, the discount is $25.31 and the purchase price is $474.69.

Exercises

Use formulas (4) and (5) in the solution of the following:

1. Find the purchase price of a $1,000, 5% bond, dividends payable annually, redeemable in 20 years at par, if the investment rate is to be 5½% convertible annually.

2. Find the purchase price of a $5,000, 4½% bond, dividends payable semi-annually, redeemable in 15 years at 102, if the investment rate is to be 4% convertible semi-annually.

3. What should be the purchase price of a $10,000, 3½% bond, dividends payable semi-annually, redeemable in 35 years at par, if 4% (convertible semi-annually) is to be realized on the investment?

4. Find the purchase price of a $500, 4½% bond, dividends payable quarterly, to be redeemed in 18 years at par, if the investment rate is to be 5% convertible quarterly.

5. What is the purchase price of a $10,000, 6% bond, dividends payable semi-annually, redeemable in 30 years at 105, the investment rate to be 4½% convertible semi-annually?

6. What should be the purchase price of a $1,000, 5% bond, dividends payable annually, to be redeemed in 10 years at 110, if the investment rate is to be 6% convertible annually?

7. Establish formula (4).

8. Use formulas (4) and (5) to solve Exercises 3 and 5, Art. 55.

9. Use formulas (4) and (5) to solve Exercise 10, Art. 55.

57. Amortization of premium and accumulation of discount.—When a bond is bought for more than the redemption value, provision should be made for restoring any excess of the original capital invested over the redemption price. The excess of interest on the bond over the interest required at the investment rate can and should be used for the gradual extinction of the excess book value* over the redemption price. The book value of a bond bought above redemption price thus diminishes at each interval until the redemption date, at which time its book value is equal to the redemption price. This amortization of the excess of purchase price over redemption price is called *amortization of the premium.*

When a bond is bought for less than the redemption price, we may think of it as having a periodically increasing book value, approaching the redemption price at maturity. The accumulation of the excess of redemption price over the purchase price is called *accumulation of the discount.* We shall illustrate by examples.

---

* The *book value* of a bond on a dividend date is the price P at which the bond would sell at a given investment rate.

Example 1. A \$1,000, 6% bond, dividends payable annually, redeemable in 6 years is bought to yield 5% annually. Find the purchase price and construct a schedule showing the amortization of the premium.

Solution. Here, $C =$ \$1,000, $n = 6$, $j = 0.05$, $m = p = 1$, and $g = 0.06$.

Hence, $$k = 0.0507569.$$

$$\text{Premium} = P - C = \$50.76.$$

And $$P = \$1,050.76.$$

Now the book value of the bond at the date of purchase is \$1,050.76. At the end of the first year a \$60 dividend is paid on the bond. However, 5% on the book value for the first year is only \$52.54. This would leave a difference of \$60 $-$ \$52.54 = \$7.46 for the amortization of premium for the first year. This would reduce the book value to \$1,043.30 for the second year. The interest on this amount at 5% is \$52.17. This leaves \$60 $-$ \$52.17 = \$7.83 for the amortization of premium for the second year, and so on.

The following schedule shows the amount of amortization each year and the successive book values.

SCHEDULE OF AMORTIZATION—SCIENTIFIC METHOD

At End of Period	Dividend on Bond	Interest Earned on Book Value	Amortization of Premium	Book Value
0	. . . . . .	. . . . . .	. . . . . .	\$1,050.76
1	\$60.00	\$52.54	\$7.46	1,043.30
2	60.00	52.17	7.83	1,035.47
3	60.00	51.77	8.23	1,027.24
4	60.00	51.36	8.64	1,018.60
5	60.00	50.93	9.07	1,009.53
6	60.00	50.48	9.52	1,000.01
Total			\$50.75	

The amortization of the premium may also be cared for by the straight line method. By this method the premium is divided by the number of periods and the book value is decreased each period by this quotient. Thus, in the present problem we would have \$50.76 $\div$ 6 = \$8.46. The following schedule illustrates the method.

SCHEDULE OF AMORTIZATION—STRAIGHT LINE METHOD

At End of Period	Dividend on Bond	Amortization	Book Value
0	......	.....	$1,050.76
1	$60.00	$8.46	1,042.30
2	60.00	8.46	1,033.84
3	60.00	8.46	1,025.38
4	60.00	8.46	1,016.92
5	60.00	8.46	1,008.46
6	60.00	8.46	1,000.00

Example 2. A \$10,000, 4% bond, dividends payable semi-annually, redeemable in 4 years, is bought to yield 5% semi-annually. Find the purchase price and construct a schedule showing accumulation of the discount.

Solution. Here, $C = \$10,000$, $n = 4$, $j = 0.05$, $m = p = 2$, and $g = 0.04$. Hence,

$$k = -0.0358506,$$

$$\text{Discount} = P - C = -\$358.51.$$

And $$P = \$9,641.49.$$

The following schedule shows the accumulation of discount for each period and the book value for each period.

SCHEDULE OF ACCUMULATION—SCIENTIFIC METHOD

At End of Period	Dividend on Bond	Interest Earned on Book Value	Accumulation of Discount	Book Value
0	....	....	....	$9,641.49
1	$200.00	$241.04	$41.04	9,682.53
2	200.00	242.06	42.06	9,724.59
3	200.00	243.11	43.11	9,767.70
4	200.00	244.19	44.19	9,811.89
5	200.00	245.28	45.28	9,857.17
6	200.00	246.43	46.43	9,903.60
7	200.00	247.59	47.59	9,951.19
8	200.00	248.78	48.78	9,999.97
Total			$358.48	

1. A $1,000, 5% bond, dividends payable semi-annually, redeemable in **7** years at par, is bought to yield 6% semi-annually. Construct an accumulation schedule.

2. A $1,000, 5% bond, dividends payable annually, redeemable in 10 years, is bought to yield 4½% annually. Construct an amortization schedule.

3. Construct a schedule for the amortization of the premium of the bond in Exercise 1, Art. 55.

4. Construct an accumulation schedule for the bond of Exercise 6, Art. 56.

5. A $500, 5% bond, pays dividends semi-annually and will be redeemed at 105 on January 1, 1946. It is bought on July 1, 1942, to yield 6% converted semi-annually. Find the purchase price and form a schedule showing the accumulation of the discount.

6. A $5,000, 6% bond, paying semi-annual dividends will be redeemed at 110 on September 15, 1947. Find the price on September 15, 1942, to yield 5% converted semi-annually, and form a schedule showing the amortization of the premium.

58. Bonds purchased between dividend dates.—We shall consider two cases.

(a) When the bond is bought at a certain *quoted price and accrued interest* with no apparent regard for yield.

(b) When the bond is bought on a *strictly yield basis.*

By accrued interest in case (a) is meant accrued *simple* interest on the *face value* at the rate named in the bond. In other words, we mean the accrued dividend. We shall illustrate by an example.

Example 1. A bond of $1,000 dated July 1, 1940, bearing 6% interest payable semi-annually, was purchased March 1, 1941, at 98.5 and accrued interest. What was paid for the bond?

Solution. The dividend dates are July 1, and Jan. 1. The *price quoted* on this bond is evidently $985.00. Hence, the price paid on March 1 is $985.00 plus the interest on $1,000 from Jan. 1 to March 1 at 6%, or

$$\$985.00 + \$10.00 = \$995.00, \text{ purchase price.}$$

The student should observe that the purchase price is equal to the quoted price plus the dividend accrued from the last dividend date to the time of purchase.

When the bond is bought at a price to yield a given rate of interest on the investment, *the purchase price is equal to the value (purchase price) of the bond at the last dividend date (the one just before the date of purchase) plus the interest, at the investment rate, on this value, from the last dividend date to the date of purchase.* In practice, ordinary simple interest is used.

If P_0 stands for the purchase price at the last dividend date and d is the number of days from the last dividend date to the date of purchase, the purchase price may be defined by the formula

$$P = P_0 + \frac{P_0 dj}{360}. \tag{6}$$

Example 2. A bond of \$500 issued March 1, 1930, at 4% payable semi-annually and to be redeemed March 1, 1947, was purchased May 10, 1938, to realize 5% (converted semi-annually) on the investment. What should have been paid for the bond? Find the quoted price.

Solution. The time from March 1, 1938 (the last dividend date) to March 1, 1947 (the redemption date), is 9 years, and the purchase price as of the last dividend date is

$$P_0 = 500(1.025)^{-18} + 10\,\frac{1 - (1.025)^{-18}}{0.025} = \$464.12.$$

The time from March 1, 1938 (the last dividend date), to May 10, 1938 (the date of purchase), is 70 days.

Hence, $\qquad \dfrac{P_0 dj}{360} = \dfrac{(464.12)(70)(0.05)}{360} = \$4.51$

and $P = 464.12 + 4.51 = \$468.63$, the purchase price on May 10, 1938.

Now, the quoted price as of May 10, 1938, is the purchase price as of that date minus the dividend accrued from March 1, 1938, to May 10, 1938. The accrued dividend is the ordinary simple interest on \$500 for 70 days at 4%, or \$3.89.

Hence, the quoted price is

$$\$468.63 - \$3.89 = \$464.74.$$

The student should observe the difference between purchase price and quoted price. Bonds are usually quoted on the market at a certain price plus accrued interest (at the dividend rate), guaranteed to yield a certain rate of interest on the investment. In the case of the above bond the quoted price as of May 10, 1938, would have been \$464.74 (or 92.95% of face) and accrued interest to yield 5% semi-annually on the investment if held to the date of redemption.

Exercises

1. A $1,000, 6% bond, dividends payable semi-annually, dated January 1, 1942, was purchased September 10, 1944, at 97.5 and accrued interest. What was paid for the bond?

2. The bond described in Exercise 1 is to mature January 1, 1949. What should have been paid for it September 10, 1944, if purchased to yield 7% semi-annually?

3. At what price should a $500, 6% semi-annual bond, dated April 1, 1939, and maturing April 1, 1946, be bought July 10, 1940, to yield $5\frac{1}{2}\%$, semi-annually, on the investment? Find the quoted price.

4. Should an investor, who wished to make 5% nominal, converted semi-annually, on his investment, have bought government bonds quoted at 89 on February 1, 1920? These bonds were redeemable November 15, 1942, and bore $4\frac{1}{4}\%$ interest, payable semi-annually.

5. On July 20, 1935, a man bought 5% semi-annual bonds, due October 1, 1945, on a 6% semi-annual basis. The interest dates were April 1 and October 1. What price did he pay? Find the quoted price for that date.

6. A $1,000, 6% bond, dividends payable March 15 and September 15, is redeemable March 15, 1950. It was bought January 1, 1944, to yield $5\frac{1}{2}\%$ converted semi-annually. Find the purchase price and the quoted price.

7. Find the quoted price for the bond of Exercise 6, as of July 5, 1947.

59. Annuity bonds.—An *annuity bond* is an interest-bearing bond, payable, principal and interest, in equal periodic payments or installments. It is evident that these equal periodic payments constitute an annuity whose present value is the face of the bond. The periodic payment can be found by using Art. 31. The purchase price at any date is the present value (figured at the investment rate) of the annuity composed of the periodic payments yet due. Let us illustrate by an example.

Example. At what price should a 4% annuity bond for $5,000, payable in 8 equal annual payments, be purchased at the end of 3 years (just after the third payment has been made), if 5% (converted annually) is to be realized on the investment?

Solution. Using Art. 31, we find the periodic payment to be

$$R = 5,000 \frac{0.04}{1 - (1.04)^{-8}} = \$742.64.$$

The purchase price at the end of 3 years is equal to the present value of an annuity of $742.64 for 5 years at 5% converted annually.

Hence, $\qquad P = 742.64 \dfrac{1 - (1.05)^{-5}}{0.05} = \$3,215.24.$

60. Serial bonds.—When selling a set of bonds, a corporation may wish to redeem them in installments instead of redeeming all of the bonds on one date. When a bond issue is to be redeemed in several installments instead of all the bonds being redeemed on one date, the issue is known as a *serial issue* and the bonds of the issue are known as *serial bonds*. Evidently, the purchase price at any date is equal to the sum of the purchase prices of the installments yet to be redeemed.

Example. A city issues \$40,000 worth of 4% bonds, dividends payable semi-annually, to be redeemed by installments of \$4,000 in 2 years, \$6,000 in 4 years, \$8,000 in 6 years, \$10,000 in 8 years and \$12,000 in 10 years. An insurance company buys the entire issue on the date of issue so as to realize 5% (converted semi-annually) on the investment. What price was paid for the entire issue?

Solution. The purchase price of the entire issue is equal to the sum of the purchase prices of the five installments to be redeemed. Using (5), Art. 56, we have

$$4{,}000 - 4{,}000(0.005)\,\frac{1 - (1.025)^{-4}}{0.025} = \$\ 3{,}924.76$$

$$6{,}000 - 6{,}000(0.005)\,\frac{1 - (1.025)^{-8}}{0.025} = \$\ 5{,}784.90$$

$$8{,}000 - 8{,}000(0.005)\,\frac{1 - (1.025)^{-12}}{0.025} = \$\ 7{,}589.69$$

$$10{,}000 - 10{,}000(0.005)\,\frac{1 - (1.025)^{-16}}{0.025} = \$\ 9{,}347.25$$

$$12{,}000 - 12{,}000(0.005)\,\frac{1 - (1.025)^{-20}}{0.025} = \$11{,}064.65$$

and $$P = \$37{,}711.25.$$

Hence, the purchase price of the issue is \$37,711.25.

Exercises

1. At what price should a 5% (payable semi-annually) annuity bond for \$10,000, payable in 26 equal semi-annual payments, be purchased at the end of 6 years, if 5½% (converted semi-annually) is to be realized on the investment?

2. A \$25,000 serial issue of 6% bonds, with semi-annual dividends, is to be redeemed by payments of \$5,000 at the end of 3, 4, 5, 6, and 7 years respectively. Find the purchase price of the entire issue, if bought now to realize 5% (converted semi-annually) on the investment. [Use (4) and (5) Art. 56.]

3. What is the purchase price of a bond of \$20,000 payable \$5,000 in 4 years, \$8,000 in 6 years, \$5,000 in 7 years, and \$2,000 in 9 years, with dividends at 5% semi-annually, if the purchaser is to receive 6%, converted semi-annually, on his investment?

4. Find the purchase price of a 10-year annuity bond for \$25,000, to be paid in semi-annual installments with interest at 6% converted semi-annually, if purchased at the end of 4 years to yield 5% converted semi-annually.

5. Find the purchase price on the date of issue of a \$2,000 bond bearing 4%, the principal and interest to be paid in 6 equal annual installments, if the purchaser is to realize 5% (convertible semi-annually) on his investment.

61. Use of bond tables.—Tables are available which give the purchase prices of bonds corresponding to given dividend rates, investment rates and times to maturity. These tables may be made as comprehensive as their purpose demands. The dividend rates may range from as low as 2 per cent to 8 or 9 per cent by intervals of ⅛ per cent. The investment rates may have about the same range, but with smaller intervals. The times to maturity may range from ¼, ½ or 1 year to 50 or 100 years by intervals of ¼, ½ or 1 year depending on whether or not the dividends are payable quarterly, semi-annually or annually. These tables may be arranged in various forms. The following is a brief portion of a bond table:

TABLE SHOWING PURCHASE PRICES OF A 4% BOND FOR \$1,000 WITH
DIVIDENDS PAYABLE SEMI-ANNUALLY

Investment Rate Converted Semi-annually	Time to Maturity			
	5 Years	10 Years	15 Years	20 Years
2.00	\$1,094.71	\$1,180.46	\$1,258.08	\$1,328.35
2.50	1,070.09	1,131.99	1,186.67	1,234.95
3.00	1,046.11	1,085.84	1,120.08	1,149.58
3.50	1,022.75	1,041.88	1,057.97	1,071.49
4.00	1,000.00	1,000.00	1,000.00	1,000.00
4.50	977.83	960.09	945.89	934.52
5.00	956.24	920.05	895.35	874.49
5.50	935.20	885.71	848.14	819.41
6.00	915.70	851.23	804.00	768.85

Example. A \$500, 4% bond, dividends payable semi-annually, redeemable in 15 years at par, is bought to yield 5½% convertible semi-annually. Find its purchase price.

Solution. Observing the above table, we find the purchase price of a \$1,000 bond corresponding to the given dividend rate, investment rate and time to maturity is \$848.14. But we are considering a \$500 bond. Consequently, its purchase price is \$424.07.

Exercises

1. Consider a \$500 bond due in 20 years, and bearing semi-annual dividend coupons at 4% per annum. Find by the use of the above table the purchase price if the investment rate is to be 4½%. Check the result by calculations independent of the table.

2. Solve Exercise 1, if the investment rate is to be (a) 3%; (b) 3½%; (c) 5%; (d) 6%.

3. Consider a \$500, 4% bond, dividends payable semi-annually, which matures in 10 years. Using the above table and the method of interpolation find the approximate purchase price when the investment rate is to be (a) 3¾% (b) 5¼%. Check (a) by using formula (5), Art. 124 and logarithms.

4. Solve Exercise 3, if the investment rate is to be (a) 3¼%; (b) 4¾%.

62. Determining the investment rate when the purchase price of a bond is given.—At times the price of a bond is quoted on the market, guaranteed to yield a certain rate of interest on the investment, provided the bond is held until the date of maturity. At other times the price is quoted, but no investment rate is given. Before purchasing a bond at a certain price, the prospective buyer would naturally want to know (approximately at least) the rate of interest that would be realized by such an investment. Therefore, it is very important that we have a method of finding the investment rate when the purchase price is given. We shall discuss two methods: (a) when bond and annuity tables are available; (b) when no tables are available.

(a) When either bond or annuity tables are given the approximate investment rate may be found by the method of interpolation. We shall illustrate by examples.

Example 1. Find the rate of income realized on a 6% bond purchased for \$105, 10 years before maturity.

Solution. Since the bond is bought at a premium the investment rate will be less than the dividend rate. Let us try 5%.

Then, $\qquad P = 100(1.05)^{-10} + 6\,\dfrac{1 - (1.05)^{-10}}{0.05}$

$\qquad\qquad = 61.39 + 46.33 = \$107.72.$

Evidently the investment rate is greater than 5%. Let us now try $5\frac{1}{2}\%$.

Then, $\qquad P = 100(1.055)^{-10} + 6\,\dfrac{1 - (1.055)^{-10}}{0.055}$

$\qquad\qquad = 58.54 + 45.23 = \$103.77.$

We observe that the investment rate must lie between 5% and $5\frac{1}{2}\%$. Arranging the results thus obtained, we have

Cost	Investment Rate
107.72	5%
105.00	$x\%$
103.77	$5\frac{1}{2}\%$

Interpolating, we have

$$\frac{107.72 - 105.00}{107.72 - 103.77} = \frac{5 - x}{5 - 5\frac{1}{2}},$$

$$\frac{2.72}{3.95} = \frac{x - 5}{\frac{1}{2}},$$

$$3.95x = 21.11,$$

$$x = 5.344\%.$$

Example 2. Find the rate of income realized on a 4% semi-annual bond, purchased for $\$94.50$, 10 years before maturity.

Solution. Try 4½%. Then,

$$P = 100(1.0225)^{-20} + 2\frac{1 - (1.0225)^{-20}}{0.0225}$$

$$= \$96.01$$

The rate is evidently greater than 4½%. We shall now try 5%.

$$P = 100(1.025)^{-20} + 2\frac{1 - (1.025)^{-20}}{0.025}$$

$$= \$92.20.$$

We observe that the rate lies between 4½% and 5%.

Cost	Investment Rate
96.01	4½%
94.50	x%
92.20	5%

Interpolating, we have

$$\frac{96.01 - 94.50}{96.01 - 92.20} = \frac{4½ - x}{4½ - 5},$$

$$\frac{1.51}{3.81} = \frac{x - 4½}{½},$$

$$1.51 = 7.62x - 34.29,$$

$$7.62x = 35.80,$$

$$x = 4.7\%.$$

The student will observe that we find a rate that gives a purchase price a little larger than the given purchase price and then a rate which gives a purchase price a little smaller than the given purchase price. We then find the approximate rate by interpolation.

Example 3. A $1,000, 4% bond, dividends payable semi-annually, was bought 20 years before maturity at $850.25. Using the above bond table, Art. 61, find the approximate investment rate.

Solution.

When $j = 0.050$, $P = \$874.49$.

When $j = 0.055$, $P = \$819.41$.

Then, $$j = 0.0500 + \frac{874.49 - 850.25}{874.49 - 819.41}(0.055 - 0.050)$$

$$= 0.0500 + \frac{24.24}{55.08}(0.005)$$

$$= 0.0500 + 0.0022 = 0.0522 = 5.22\%.$$

Exercises

1. Find the rate of income realized on a 5% semi-annual bond maturing in $18\frac{1}{2}$ years when bought at $103.35.

2. A $1,000, 5% bond with semi-annual dividends, is redeemable at par at the end of 12 years. If it is quoted at $1,075.60, what is the investment rate?

3. Find the effective rate realized by investing in 5% bonds with semi-annual dividends, redeemable at par, which are quoted at 84.2, 10 years before redemption.

4. A state bond bearing 5% interest, payable semi-annually, and redeemable in 8 years at par, was sold at 95. Find the yield rate.

5. On November 15, 1930, a certain United States Government bond sold at 90. If this bond is redeemable November 15, 1952, and bears 4% interest, payable semi-annually, find the yield rate on November 15, 1930.

6. A 4% bond, dividends payable semi-annually, was bought 15 years before maturity at 92.5. Using the bond table, find the approximate investment rate.

7. Using the bond table, find the approximate investment rate, when a 4% bond, dividends payable semi-annually, is bought 10 years before maturity at 106.3.

(b) When tables are not available the approximate investment rate may be found by solving formula (4), Art. 56 for j. This formula may be written

$$\frac{g - j}{k} = \frac{j}{1 - \left(1 + \dfrac{j}{p}\right)^{-np}}. \tag{7}$$

Expanding $\left(1 + \dfrac{j}{p}\right)^{-np}$ by the binomial theorem and neglecting all terms that involve j^3 and higher powers of j, we get

$$\left(1 + \frac{j}{p}\right)^{-np} = 1 - nj + \frac{np(np+1)}{2} \cdot \frac{j^2}{p^2},$$

and

$$\frac{g-j}{k} = \frac{j}{nj - \dfrac{n(np+1)}{2p}j^2} = \frac{1}{n - \dfrac{n(np+1)j}{2p}}.$$

Multiplying the above equation through by n and dividing out the right-hand member, we obtain

$$\frac{n(g-j)}{k} = 1 + \frac{np+1}{2p}\, j \text{ (approximately).}$$

Solving for j, we have

$$j = \frac{2p(ng - k)}{np(k + 2) + k}, \tag{8}$$

which will give the approximate investment rate.

Example 4. Let us now apply formula (8) to Example 1, of Art. 62.

Solution. Here, $k = 0.05$, $n = 10$, $p = 1$, and $g = 0.06$.

Then,
$$j = \frac{2(0.60 - 0.05)}{10(2 + 0.05) + 0.05} = 0.05353,$$

and the approximate investment rate is 5.353%.

We notice that the result obtained by using formula (8) is approximately the same as that obtained by using annuity tables.

Ordinarily, (8) will give a result which is accurate enough. At least, it is accurate enough for the layman who might be interested in the purchasing of bonds. Naturally, bond houses and individuals dealing in bonds and quoting bond prices, to yield a certain rate of interest on the investment, would require a more accurate method. However, these people would have comprehensive bond and annuity tables available, by which the investment rate could be found to the required degree of accuracy.

Exercises

1. Apply formula (8) to Examples 2 and 3 of Art. 62.

2. Apply formula (8) to Exercises 1, 3, and 5 of Art. 62(a), page 158.

3. Apply formula (8) to Exercises 2, 4, and 6 of Art. 62(a), page 158.

4. A person bought a $1,000, 5% bond, dividends payable semi-annually, 18 years before maturity for $975. Find the investment rate by using annuity tables and then check the result by using formula (8).

5. A $500, 3¼% Government bond, dividends payable June 15 and December 15, was bought June 15, 1945, for $530. If this bond is to be redeemed December 15, 1956, find the investment rate as of June 15, 1945.

Problems

1. A $1,000, 5% bond, dividends payable April 15 and October 15, maturing October 15, 1946, was bought April 15, 1943, to yield $(j = .06, m = 2)$. Construct a schedule showing the accumulation of the discount.

2. A $1,000, 6% bond, dividends payable semi-annually, maturing in 4 years, was bought to yield $(j = .05, m = 2)$. Construct a schedule showing the amortization of the premium.

3. A $300,000 issue of highway bonds bearing 4% interest, payable semi-annually, dated January 1, 1944, matures $100,000 January 1, 1945, 1946 and 1947. What price should be paid for the issue to realize $(j = .03, m = 2)$?

4. A $1,000 bond paying 5% semi-annually, redeemable at $1,040 in 10 years, has been purchased for $970. Find the investment rate.

5. A 4%, J. and J.,* bond is redeemable at par on January 1, 1952. Find the yield if it is purchased July 1, 1939, at 89.32.

6. A $1,000, 6%, J. and J., bond is redeemable at par on July 1, 1950. Find the price to yield $(j = .05, m = 2)$ on August 16, 1940.

7. Find the purchase price of a $100, 5% bond, dividends payable semi-annually and redeemable at par in 10 years, to yield 6% effective.

8. Find the purchase price of a $100, 4% bond, dividends payable semi-annually and redeemable in 20 years at 120, to yield 5% effective.

* That is, the dividends are payable January 1 and July 1.

CHAPTER VII

PROBABILITY AND ITS APPLICATION IN LIFE INSURANCE

63. The history of probabilities.—Aristotle (384–322 B. C.), the Greek philosopher, is credited with the first attempt to define the measure of a probability of an event. Aristotle says an event is probable when the majority, or at least the majority of the most intellectual persons, deem it likely to happen.

But the first real mathematical treatment of probability originated as isolated problems coming from games of chance. Cardan (1501–1576) and Galileo, two Italian mathematicians, solved many problems relating to the game of dice. Aside from his regular occupation as a mathematician, Cardan was also a professional gambler. As such he had evidently noticed that there was always more or less cheating going on in the gambling houses. This led him to write a little treatise on gambling in which he discussed some mathematical questions involved in the games of dice then played in the Italian gambling houses. The aim of this little book was to fortify the gamester against such cheating practices. Galileo was not a gambler, but was often consulted by a certain Italian nobleman on problems relating to the game of dice. As a result of these consultations and his investigations he has left a short memoir. Pascal (1623–1662) and Fermat (1601–1665), two great French mathematicians, were also consulted by professional gamblers and this led them to make their contributions to the subject of chance.

The Dutch physicist, Huyghens (1629–1695), and the German mathematician, Leibnitz (1646–1716), also wrote on chance. However, the first extensive treatise on the subject of chance was written by Jacob Bernoulli (1654–1705). In this treatment of the subject which was published in 1713, the author shows many applications of the new science to practical problems.

The first English treatise on probabilities was written by Abraham de Moivre (1667–1754). This was a remarkable treatment and may yet be read with profit. This book was translated into German by the Austrian mathematician, E. Czuber.

It was left for La Place (1749–1827), that great French mathematician, to leave the one really famous treatise on the theory of chance, "Théorie Analytique des Probabilitiés." Since the time of La Place many books and articles on the theory have been written by mathematicians in all lands.

The subject of probability has become so widespread in its applications that the best minds of the world have undertaken its further development. Today, the physicist, the chemist, the biologist, the statistician, the actuary, depend upon the results of the theory of probability for the development of their respective fields.

Probably the earliest writer on the application of the theory of probability to social phenomena was John Graunt (1620–1674) who, in 1662, published his "Observations on the London Bills of Mortality." The astronomer, Edmund Halley, published his Mortality Tables in 1693. Adolphe Quetelet (1796–1874) devoted his life to the applications of probabilities to scientific research, particularly to the study of populations.

Following the work of these investigators, life insurance organizations began to function. With the organization of the Equitable Society of London in 1762, life insurance was successfully placed on a scientific basis. The company employed the mathematician, Dr. Richard Price, to be the actuary to determine the premiums which should be charged. He drew up the Northampton Table of Mortality in 1783, and from this event insurance as a science may be said to date.

64. Meaning of *a priori* probability.—A box contains three white and four black balls. One ball is drawn at random and then replaced and this process is continued indefinitely. What proportion of the balls drawn will be black? Here there are seven balls to be drawn or we may say there are seven possibilities, and either of the seven balls is *equally likely* to be drawn or any one of the seven possibilities is *equally likely* to happen. Of the seven possibilities, any one of three would result in drawing a white ball and any one of four would result in drawing a black ball. We would say then that three possibilities of the seven are favorable to drawing a white ball and the other four possibilities are favorable to drawing a black ball. We put the above statement in another way by saying that in a single draw the probability of drawing a white ball is $\frac{3}{7}$ and the probability of drawing a black ball is $\frac{4}{7}$. This does not mean that out of only seven draws, exactly three would be white and four black. But it does mean that, if a single ball were drawn at random and were replaced and this process continued indefinitely, $\frac{3}{7}$ of the balls drawn would be white and $\frac{4}{7}$ would be black. Or the ratio of the number of white balls drawn to the number of black balls drawn would be as 3 to 4.

Reasoning similarly to the above led La Place to formulate the following *a priori* definition of probability:

If h is the number of possible ways that an event will happen and f is the number of possible ways that it will fail and all of the possibilities are *equally likely*, the probability that the event will happen is $p = \dfrac{h}{h + f}$ and the probability that it will fail is $q = \dfrac{f}{h + f}$.

It is evident, then, that the sum of the probability that an event will happen and the probability that it will fail is 1, the symbol for certainty.

In analyzing a number of possibilities we must be sure that each of them is *equally likely* to happen before we attempt to apply the above definition of probability.

Example: What is the probability that a man aged 25 and in good health will die before age 30? In this case we might reason thus: The event can happen in only one way and fail in only one way, and consequently the probability that he will die before age 30 is ½. But this reasoning is false for we are assuming that living five years and dying within five years are *equally likely* for a man now 25 years old. But this is not the actual experience. This example will be discussed in Art. 65.

Exercises

1. A bag contains 7 white and 5 black balls, and a ball is drawn at random. What is the probability (a) that the ball is white? (b) that the ball is black?

2. A deck of 52 cards contains 4 aces. If a card is drawn at random, what is the probability that it will be an ace?

3. A coin is tossed. What is the probability that it will fall head up?

4. If the probability of winning a game is ⅗, what is the probability of losing?

5. If the probability of a man living 10 years is 0.6, what is the probability of his dying within 10 years?

6. If a cubical die is tossed, what is the probability that it will fall with 6 up?

7. Two coins are tossed at random. What is the probability of obtaining (a) two heads? (b) one head and one tail?

8. Two cubical dice are tossed at random. Find the probability that the sum of the numbers is 2; 3; 4; 5; 6; 7; 8; 9; 10; 11; 12.

9. A box contains 45 tickets numbered from 1 to 45. If a ticket is drawn at random, what is the probability that the number on it is (a) odd? (b) even? (c) divisible by 5? (d) larger than 35?

10. A coin and a cubical die are tossed simultaneously. Find the probability that they will fall with the coin head up and with a face on the die numbered less than 5.

11. Three coins are tossed. What is the probability of exactly two heads?

12. Which is the more likely to happen, a throw of 4 with one die or a throw of 8 with two dice?

13. A and B each throw two dice. If A throws 8, find the probability that B will throw a larger number.

65. Relative frequency. Empirical probability.—In the example and the exercises of Art. 64 the probabilities are derived in each case by an *a priori* determination of all the equally likely ways in which the event in question can happen. There are many classes of events in which the notion of probability is important although it is impossible to make an *a priori* determination of all the equally likely ways an event can happen or fail. In such cases we determine an approximate probability empirically by means of a large number of observations. Such determinations are necessary in the establishment of life insurance, pension systems, fire insurance, casualty insurance, and statistics.

If we have observed that an event has happened h times out of n possible ways, we call h/n the *relative frequency* of the event. When n is a large number, h/n may be considered a fair estimate of the probability derived from observation. Our confidence in the estimate increases as the number n of observed cases increases. If, as n increases indefinitely, the ratio h/n approaches a limiting value, this limiting value is the probability of the happening of the event. That is

$$p = \frac{\text{limit}}{n \to \infty} \frac{h}{n}.$$

In statistical applications the limit of h/n cannot in general be determined, but satisfactory approximations to the limit may be found for many practical purposes.

We are now ready to solve the problem which was stated in Art. 64. The American Experience Table of Mortality shows that out of 89,032 men living at age 25, the number living at age 30 will be 85,441. Then the number dying before age 30 is 89,032 − 85,441 or 3,591. Hence the probability that a man aged 25 will die before age 30 is $\dfrac{3,591}{89,032} = .0403$. In this problem, n equals 89,032 and h equals 3,591.

We have previously stated that the value h/n is only an estimate, but it is accurate enough (when n is a large number) for many practical purposes. Life insurance companies use the American Experience Table of Mortality as a basis to determine the proper premiums to charge their policy holders.

1. Among 10,000 people aged 30, 85 deaths occurred in a year. What was the relative frequency of deaths for this group?

2. Out of 10,000 children born in a city in a given year, 5,140 were boys and 4,860 were girls. What was the relative frequency of boy babies in the city that year?

3. A group of 10,000 college men was measured as to height. Of these, 1,800 were between 68 and 69 inches high. Estimate the relative frequency of height of college men between 68 and 69 inches.

66. Permutations. Number of permutations of things all different.— Each of the different ways that a number of things may be arranged is known as a *permutation* of those things. For example the different arrangements of the letters *abc* are: *abc, acb, bac, bca, cab, cba*. Here there are 3 different ways of selecting the first letter and after it has been selected in one of these ways there remain 2 ways of selecting the second letter. Then the first two letters may be selected in $3 \cdot 2$ or 6 ways. It is clear that we have no choice in the selection of the third letter and consequently the total number of permutations (or arrangements) of the three letters is 6. This example illustrates the following:

Fundamental Principle: *If one thing may be done in p ways and after it has been done in one of these ways, another thing may be done in q ways, then the two things together may be done in the order named in pq ways.*

It is evident that for each of the p ways of doing the first thing there are q ways of doing the second thing and the total number of ways of doing the two in succession is pq.

The above principle may be extended to three or more things.

1. If 2 coins are tossed, in how many ways can they fall?

2. If 3 coins are tossed, in how many ways can they fall?

3. If 2 dice are thrown, in how many ways can they fall?

4. If 2 dice and 3 coins are tossed, in how many ways can they fall?

5. How many signals can be made by hoisting 3 flags if there are 9 different flags from which to choose?

6. In how many different ways can 3 positions be filled by selections from 15 different people?

7. How many four-digit numbers can be formed from the numbers 1, 2, 3, 4, 5, 6, 7, 8, 9?

Now suppose there are n things all different and we wish to find the number of permutations of these things taken r at a time, $n \geqq r$.

Since only r of the n things are to be used at a time, there are only r places to be filled. The first place may be filled by any one of the n things and the second place by any one of the $n - 1$ remaining things. Then the first and second places together may be filled in $n(n - 1)$ ways. The third place may be filled by any one of the $n - 2$ remaining things. Hence the first three places may be filled in $n(n - 1)(n - 2)$ ways. Reasoning in a similar way we see that after $r - 1$ places have been filled, there remain $n - (r - 1)$ things from which to fill the rth place. Applying the fundamental principle stated above we have

$$*_nP_r = n(n - 1)(n - 2) \cdots (n - r + 1). \tag{1}$$

When $r = n$, (1) becomes,

$$_nP_n = n(n - 1)(n - 2) \cdots 3 \cdot 2 \cdot 1 = \dagger n!. \tag{2}$$

Exercises

1. A man has two suits of clothes, four shirts and three hats. In how many ways may he dress by changing suits, shirts and hats?

2. How many arrangements of the letters in the word "Mexico" can be made, using in each arrangement (a) 4 letters? (b) all the letters?

3. Four persons enter a street car in which there are 7 vacant seats. In how many ways may they be seated?

4. Three different positions in an office are to be filled and there are 15 applicants, each one being qualified to fill any one of the positions. In how many ways may the three positions be filled?

5. How many signals could be made from 5 different flags?

6. Find the number of permutations, P, of the letters $a\,a\,b\,b\,b$ taken 5 at a time. Hint: $P \cdot 2! \cdot 3! = 5!$.

7. If P represents the number of distinct permutations of n things, taken all at a time, when, of the n things, there are n_1 alike, n_2 others alike, n_3 others alike, etc., then:

$$P = \frac{n!}{n_1! n_2! n_3! \ldots}.$$

8. How many distinct permutations can be made of the letters of the word *attention* taken all at a time?

9. How many distinct permutations of the letters of the word *Mississippi* can be formed taking the letters all at a time?

---

* The symbol $_nP_r$ is used to denote the number of permutations of n things taken r at a time.

$\dagger$ $n!$ is a symbol which stands for the product of all the integers from 1 up to and including n, and is read "factorial n."

10. How many ways can ten balls be arranged in a line if 3 are white, 5 are red, and 2 are blue?

11. How many six-place numbers can be formed from the digits 1, 2, 3, 4, 5, 6, if 3 and 4 are always to occupy the middle two places?

12. In how many ways can 3 different algebras and 4 different geometries be arranged on a shelf so that the algebras are always together?

13. In how many ways can 10 boys stand in a row when:

    (a) a given boy is at a given end?
    (b) a given boy is at an end?
    (c) two given boys are always together?
    (d) two given boys are never together?

67. Combinations. Number of combinations of things all different.— *By a combination we mean a group of things without any regard for order of arrangement of the individuals within the group.* For example *abc, acb, bac, bca, cab, cba* are the same combination of the letters *abc*, but each arrangement is a different permutation.

By the number of combinations of n things taken r at a time is meant the number of different groups that may be formed from n individuals when r individuals are placed in each group. For example *ab, ac,* and *bc* are the different combinations of the letters *abc* when two letters are used at a time.

The symbol $_nC_r$ is universally used to stand for the number of combinations of n things taken r at a time. We will now derive an expression for $_nC_r$. For each one of the $_nC_r$ combinations there are $r!$ different permutations. And for all of the $_nC_r$ combinations there are $_nC_r \cdot r!$ permutations, which is the number of permutations of n things taken r at a time. Hence,

$$_nC_r \cdot r! = {_nP_r},$$

and

$$_nC_r = \frac{_nP_r}{r!}. \tag{3}$$

Since

$$_nP_r = n(n-1)(n-2)\cdots(n-r+1),$$

we have

$$_nC_r = \frac{n(n-1)(n-2)\cdots(n-r+1)}{r!} \tag{4}$$

$$= \frac{n!}{r!(n-r)!} \tag{4'}$$

1. Find the number of combinations of 10 things taken 7 at a time:

Solution. Here, $n = 10$ and $r = 7$.

Then,
$$_{10}C_7 = \frac{10 \cdot 9 \cdot 8 \cdot 7 \cdot 6 \cdot 5 \cdot 4}{7 \cdot 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2} = 120.$$

2. How many committees of 5 can be selected from a group of 9 men?

3. Out of 8 Englishmen and 5 Americans how many committees of 3 Englishmen and 2 Americans can be chosen?

4. How many different sums can be made up from a cent, a nickel, a dime, a quarter, and a dollar?

5. An urn contains 5 white and 7 black balls. If 4 balls are drawn at random what is the probability that (a) all are black, (b) 2 are white and 2 are black?

Solution. (a) The total number of ways that 4 balls may be drawn from 12 balls is $_{12}C_4$ or 495 ways. And the number of ways that 4 black balls may be drawn is $_7C_4$ or 35 ways. Hence the probability of drawing 4 black balls is $^{35}\!/_{495}$ or $\frac{7}{99}$.

(b) Two white balls may be drawn in $_5C_2$ or 10 ways. And for each one of these 10 ways of drawing two white balls, two black balls may be drawn in $_7C_2$ or 21 ways. Then two white balls and two black balls may be drawn together in 10×21 or 210 ways (Fundamental Principle, Art. 66). Hence, the probability of drawing 2 white and 2 black balls is $^{210}\!/_{495}$ or $\frac{14}{33}$.

6. A bag contains 4 white, 6 black, and 7 red balls. If 4 balls are drawn at random, what is the probability that (a) all are black, (b) 2 black and 2 red, (c) 1 white, 1 black, and 2 red?

7. Prove that $_nC_r = {}_nC_{n-r}$.

8. Prove that the expansion of the binomial $(a + b)^n$ may be written

$$(a + b)^n = a^n + {}_nC_1 a^{n-1}b + {}_nC_2 a^{n-2}b^2 + \cdots + {}_nC_r a^{n-r}b^r + \cdots + b^n$$

$$= \sum_{r=0}^{r=n} {}_nC_r a^{n-r}b^r,$$

if we define $_nC_0$ to be 1.

9. How many straight lines are determined from 10 points, no 3 of which are in the same straight line?

10. How many different sums can be made from a cent, a nickel, a dime, a quarter, a half-dollar, and a dollar?

11. From 10 books, in how many ways can a selection of 6 be made: (a) when a specified book is always included? (b) when a specified book is always excluded?

12. Prove that $_nC_r + {}_nC_{r-1} = {}_{n+1}C_r$.

13. Out of 6 different consonants and 4 different vowels, how many linear arrangements of letters, each containing 4 consonants and 3 vowels, can be formed?

14. A lodge has 50 members of whom 6 are physicians. In how many ways can a committee of 10 be chosen so as to contain at least 3 physicians?

15. In the equation of Exercise 8, make $a = b = 1$, and show that

$$_nC_1 + {_nC_2} + \cdots + {_nC_n} = 2^n - 1.$$

16. Solve Exercise 4 above, using Exercise 15.

17. In how many ways can 7 men stand in line so that 2 particular men will not be together?

18. A committee of 7 is to be chosen from 8 Englishmen and 5 Americans. In how many ways can a committee be chosen if it is to contain: (a) just 4 Englishmen? (b) at least 4 Englishmen?

19. Prove: $_{n+2}C_{r+1} = {_nC_{r+1}} + 2 \cdot {_nC_r} + {_nC_{r-1}}$.

20. If $_nP_r = 110$ and $_nC_r = 55$, find n and r.

21. If $_nC_4 = {_nC_2}$, find n.

22. If $_nC_3 = 10/21({_nC_5})$, find n.

23. If $_{2n}C_{n-1} = 91/24({_{2n-2}C_n})$, find n.

24. Prove: $_nC_1 + 2 \cdot {_nC_2} + 3 \cdot {_nC_3} + \cdots + n \cdot {_nC_n} = n(2)^{n-1}$.

25. How many line-ups are possible in choosing a baseball nine of 5 seniors and 4 juniors from a squad of 8 seniors and 7 juniors, if any man can be used in any position?

68. Some elementary theorems in probability.—Sometimes it is convenient to consider an event as made up of simpler events. The given event is then said to be *compound*. Thus, the compound event may be made of simpler *mutually exclusive events*, simpler *independent events*, or simpler *dependent events*.

A. Mutually Exclusive Events. Two or more events are said to be mutually exclusive when the occurrence of any one of them excludes the occurrence of any other. Thus, in the toss of a coin the appearance of heads and the appearance of tails are mutually exclusive. Also, if a bag contains white and black balls and a ball is drawn, the drawing of a white ball and the drawing of a black ball are mutually exclusive events.

Theorem. *Mutually exclusive events. If p_1, p_2,..., p_r are the separate probabilities of r mutually exclusive events, the probability that one of these events will happen on a particular occasion when all of them are in question is*

$$P = p_1 + p_2 + p_3 + \ldots + p_r, \tag{5}$$

the sum of the separate probabilities.

This theorem follows from the definition of mutually exclusive events.

For if a_1, a_2, a_3, $\cdots$, a_r, indicate the number of ways the separate events can happen, then the number of ways favorable to some event

is $a_1 + a_2 + a_3 + \cdots + a_r$. If m represents the total number of possibilities, favorable and unfavorable, then

$$P = \frac{a_1 + a_2 + a_3 + \cdots + a_r}{m} = \frac{a_1}{m} + \frac{a_2}{m} + \frac{a_3}{m} + \cdots + \frac{a_r}{m}$$

$$= p_1 + p_2 + p_3 + \cdots + p_r.$$

When two mutually exclusive events are in question, the probabilities are frequently called *either or* probabilities. Thus, if a die is thrown, the probability of *either* an ace *or* a deuce is ⅙ + ⅙ or ⅓.

B. Independent Events. Two or more events are *dependent* or *independent* according as the occurrence of any one of them does or does not affect the occurrence of the others. Thus, if A tosses a coin and B throws a die, the tossing of heads by A and the throwing of a deuce by B are independent events. However, if a bag contains a mixture of white and black balls and a ball is drawn and not returned to the bag, the probabilities in a second drawing will be dependent upon the first event.

Theorem. *Independent events. If p_1, $p_2, \ldots, p_r$ are the separate probabilities of r independent events, the probability that all of these events will happen together at a given trial is the product of their separate probabilities.*

Let $p_1 = a_1/m_1, p_2 = a_2/m_2, \ldots, p_r = a_r/m_r$ be the simple probabilities; where $a_1, a_2, \ldots, a_r$ are the ways favorable to the happening of the separate events; and $m_1, m_2, \ldots, m_r$ are the possible ways in which the separate events may happen or fail. By the Fundamental Principle, Art. 66, the number of ways favorable to the happening together of the r events is $a_1 a_2 \ldots a_r$. And by applying the same principle we get $m_1 m_2 \ldots m_r$ as the number of possible ways that the r events might happen or fail. Consequently,

$$P = \frac{a_1 a_2 \cdots a_r}{m_1 m_2 \cdots m_r}$$

$$= p_1 p_2 \cdots p_r, \tag{6}$$

and the theorem is proved.

Corollary. *If p_1, $p_2, \ldots, p_r$ are the separate probabilities of r independent events, the probability that they will all fail on a given occasion is*

$$(1 - p_1)(1 - p_2) \ldots (1 - p_r), \tag{7}$$

and the probability that the first k events will succeed and the remainder fail is

$$p_1 p_2 \ldots p_k (1 - p_{k+1}) \ldots (1 - p_r). \tag{8}$$

C. Dependent events. The following theorem for dependent events may be proved by a similar method to that used for independent events.

Theorem. *Dependent events. Let p_1 be the probability of a first event; let p_2 be the probability of a second event after the first has happened; let p_3 be the probability of a third event after the first two have happened; and so on. Then the probability that all of these events will occur in order is*

$$P = p_1 p_2 \ldots p_r. \tag{9}$$

Exercises

1. The probability that A will live 20 years is $\frac{1}{7}$, the probability that B will live 20 years is $\frac{1}{6}$, and the probability that C will live 20 years is $\frac{1}{5}$. What is the probability that all three will be living in 20 years?

Solution. We have here three independent events, where

$$p_1 = \tfrac{1}{7}, \quad p_2 = \tfrac{1}{6}, \quad \text{and} \quad p_3 = \tfrac{1}{5}.$$

Hence, $\qquad\qquad P = (\tfrac{1}{7})\,(\tfrac{1}{6})\,(\tfrac{1}{5}) = \tfrac{1}{210}.$

2. Find the probability of drawing 2 white balls in succession from a bag containing 4 white and 7 black balls, if the first ball drawn is not replaced before the second drawing is made.

Solution. We have here two dependent events. The probability that the first draw will be white is $\dfrac{4}{4+7} = \dfrac{4}{11}$; the probability that the second draw will be white is $\dfrac{3}{3+7} = \dfrac{3}{10}.$

Hence, $\qquad\qquad p_1 = \tfrac{4}{11}, \quad p_2 = \tfrac{3}{10},$

and $\qquad\qquad P = (\tfrac{4}{11})\,(\tfrac{3}{10}) = \tfrac{6}{55}.$

3. A and B, with others, are competitors in a race. The probability that A will win is $\frac{1}{4}$ and the probability that B will win is $\frac{1}{3}$. What is the probability that either A or B will win?

Solution. We have here two mutually exclusive events.

Hence, $\qquad\qquad P = \tfrac{1}{3} + \tfrac{1}{4} = \tfrac{7}{12}.$

4. Four coins are tossed at once. What is the probability that all will be heads?

5. A bag contains 3 white balls, 4 black balls and 5 red balls. One ball is drawn and not replaced, then a second ball is drawn and not replaced and then a third ball is drawn. What is the probability (a) that a ball of each color will be drawn, (b) that 2 blacks and 1 red will be drawn, (c) that all will be red?

6. Suppose that in Exercise 5 the balls are replaced after each draw. Then answer (a), (b) and (c).

7. Three men ages 28, 30 and 33 respectively form a partnership. What is the probability (a) that all three will be living at the end of 10 years, (b) that the first two

will be living, (c) that one only of the three will be living?   Use the American Experience Table of Mortality, Table XI.

8. A man and wife are 29 and 25 years of age when they marry.   What is the probability that they will both live to celebrate their golden wedding?

9. A, B, and C go bird-hunting.   A has a record of 1 bird out of 2, B gets 2 out of 3, and C gets 3 out of 4.   What is the probability that they will kill a bird at which all shoot simultaneously?

10. If the probability that A will die within a year is $\frac{2}{10}$ and the probability that B will die within a year is $\frac{3}{10}$, what is the probability that (a) both A and B will die within a year?   (b) both A and B will live a year?   (c) one life will fail within a year? (d) at least one life will fail within a year?

11. The probability that A will solve a problem is $\frac{1}{3}$ and that B will solve it is $\frac{2}{3}$. What is the probability that if A and B try the problem will be solved?

12. From a group of 6 men and 5 women, a committee of 5 is chosen by lot.   What is the probability that it will consist of (a) all women?   (b) all men?   (c) 3 men and 2 women?

13. A committee of 7 is chosen from a group of 8 Englishmen and 5 Americans. What is the probability that it will contain (a) exactly 4 Englishmen?   (b) at least 4 Englishmen?

14. From a lottery of 30 tickets marked 1, 2, ... , 30, four tickets are drawn.   What is the probability that the numbers 1 and 15 are among them?

15. From a pack of 52 cards, 3 cards are drawn at random.   What is the probability that they are all clubs?

69. Mathematical expectation.—The *expected number of occurrences* of an event in n trials is defined to be np where p is the probability of occurrence of the event in a single trial.

Illustrations.   If 100 coins are thrown or if one coin is thrown 100 times, theoretically, we " expect " 50 heads and 50 tails, for $n = 100$ and $p = \frac{1}{2}$.

If a die is rolled 36 times we " expect " an ace to turn up 6 times, for $n = 36$ and $p = \frac{1}{6}$.

If 0.008 is the probability of death within a year of a man aged 30, the " expected " number of deaths within a year among 10,000 men of this age would be 80, for $n = 10{,}000$ and $p = 0.008$.

If p is the probability of obtaining a sum of money, k, then pk represents the *mathematical expectation.*

Illustration.   Suppose that 1,000 men, all aged 30, contribute to a fund with the understanding that each survivor will receive $1,000 at age 60.   The mortality tables show that approximately 678 will be alive. Hence, the expectation of each would be $678.   The fund must contain $678,000 in order that each survivor receive $1,000.   Hence, neglecting interest, each of the 1,000 men will have to contribute $678 to the fund.

70. Repeated trials.—When the probability that an event will happen in a single trial is known, it becomes a question of importance to determine the probability that the event will happen a specified number of times in a given number of trials.

To familiarize us with the method of proof of the general theorem of repeated trials, let us consider the

Example. What is the probability of throwing 2 aces in 4 throws of a die?

The conditions of the problem are met if in the first 2 throws we obtain aces and in the next 2 throws not-aces; or if in the first throw we get ace, the second throw not-ace, the third throw ace, and the fourth throw not-ace; and so on. We shall illustrate the possibilities symbolically as follows:

$$A_1A_2 - -, \; A_1 - A_3 -, \; A_1 - - A_4, \; - A_2A_3 -, \; - A_2 - A_4, \; - - A_3A_4$$

Considering the first case, the probability of throwing an ace on any throw is $\frac{1}{6}$. The probability of not throwing an ace on any throw is $\frac{5}{6}$. Hence the probability of throwing an ace on the first and second throws and not throwing an ace on the two remaining throws is $(\frac{1}{6})^2(\frac{5}{6})^2$.

In the second case, the probability of events occurring as the symbol above indicates is $(\frac{1}{6})(\frac{5}{6})(\frac{1}{6})(\frac{5}{6}) = (\frac{1}{6})^2(\frac{5}{6})^2$.

The remaining cases may be treated in a similar manner, and in each instance the result for any specified set is $(\frac{1}{6})^2(\frac{5}{6})^2$. Now it is evident that the 2 aces can be selected from the 4 possible aces in $_4C_2 = 6$ ways. Since the 6 cases are mutually exclusive, the chance that one or the other of the specified cases occurs is $6(\frac{1}{6})^2(\frac{5}{6})^2 = {}^{150}\!/_{1296}$.

Let us now consider the important

Theorem of Repeated Trials. *If p is the probability of the success of an event in a single trial and q is the probability of its failure, $(p + q = 1)$, then the probability P_r that the event will succeed exactly r times in n trials is*

$$P_r = {}_nC_r p^r q^{n-r}. \tag{10}$$

For the probability that the event will succeed in each of r specified trials and will fail in the remaining $(n - r)$ trials is, by (6), $p^r q^{n-r}$. Further, it is possible for the r successes to occur out of n trials in $_nC_r$ different ways. These ways being mutually exclusive, by (5) the probability in question is $P_r = {}_nC_r p^r q^{n-r}$.

---

* It will be noted that (10) is the $(n - r + 1)$th term of the expansion $(p + q)^n$ and the $(r + 1)$th term of the expansion $(q + p)^n$.

The various probabilities are indicated in the following table:

VALUES OF P_r FOR VARIOUS VALUES OF r

r	P_r	The Probability That in n Trials There Will Be		
n	p^n	n	successes, 0	failures
$n-1$	$_nC_1p^{n-1}q$	$n-1$	" , 1	"
$n-2$	$_nC_2p^{n-2}q^2$	$n-2$	" , 2	"
. . . . .	. . . .	. . . ., ...		
. . . . .	. . . .	. . . ., ...		
$n-r$	$_nC_rp^{n-r}q^r$	$n-r$ successes, r	failures	
. . . . .	. . . .	. . . . . " , ...	"	
r	$_nC_rp^r q^{n-r}$	r	" , $n-r$	"
. . . . .	. . . .	. . . . . " , ...	"	
2	$_nC_2p^2q^{n-2}$	2	" , $n-2$	"
1	$_nC_1pq^{n-1}$	1	" , $n-1$	"
0	q^n	0	" , n	"
Total....	$(p+q)^n = 1$			

From the above table we have at once the following:

Corollary. *The probability that an event will succeed at least r times in n trials is $P_r + P_{r+1} + \cdots + P_n$, that is:*

$$\sum_r^n P_r = p^n + {}_nC_1p^{n-1}q + {}_nC_2p^{n-2}q^2 + \ldots + {}_nC_rp^rq^{n-r}. \quad (11)$$

It will be noted that (11) consists of the first $(n - r + 1)$ terms of the expansion $(p + q)^n$.

Example 1. An urn contains 12 white and 24 black balls. What is the probability that, in 10 drawings with replacements, exactly 6 white balls are drawn?

Solution. We have:

$$p = {}^{12}/_{36} = \frac{1}{3}, \quad q = {}^{24}/_{36} = \frac{2}{3},$$

$$n = 10, \quad r = 6, \quad n - r = 4.$$

Hence,

$$P_6 = {}_{10}C_6\left(\frac{1}{3}\right)^6\left(\frac{2}{3}\right)^4 = \frac{3360}{3^{10}}.$$

Example 2. The American Experience Mortality Table states that for an individual aged 25 the probability of survival a year is $p = 0.992$ and the probability of death within a year is $q = 0.008$. Out of a group of 1,000 individuals aged 25, how many are expected to survive a year? What are some conclusions that may be drawn from the terms of the binomial expansion $(.992 + .008)^{1,000}$?

Solution. We have $n = 1,000$, $p = 0.992$, $q = 0.008$. By Art. 69, we expect $np = 1,000(0.992) = 992$ to survive the year, and $nq = 1,000(0.008) = 8$ to die within a year.

The terms of the expansion

$$(.992 + .008)^{1,000} = (.992)^{1,000} + 1,000(.992)^{999}(.008)$$
$$+ {}_{1,000}C_2(.992)^{998}(.008)^2 + \ldots + (.008)^{1,000}$$

give, by equation (10), the following probabilities:

$(.992)^{1,000}$ gives the probability that 1,000 will survive a year; $1,000(.992)^{999}(.008)^1$ gives the probability that 999 will live a year and 1 will die within a year, and so on.

Problems

1. If there are five routes from London to Cambridge, and three routes from Cambridge to Lincoln, how many ways are there of going from London to Lincoln going by the way of Cambridge?

2. Out of 20 boys and 25 girls, in how many ways can a couple be selected?

3. A committee of 5 is to be chosen from 15 Englishmen and 18 Americans. If the committee is to contain exactly 3 Americans and 2 Englishmen, in how many ways may it be chosen?

4. From 10 Democrats and 8 Republicans a committee of 3 is to be selected by lot. Find the probability that it will consist (a) of 2 Democrats and 1 Republican, (b) of 2 Republicans and 1 Democrat, (c) of 3 Democrats, (d) of 3 Republicans. What is the sum of the four answers?

5. Out of a party of 12 ladies and 15 gentlemen, in how many ways can 4 ladies and 4 gentlemen be selected for a dance?

6. In how many ways can 3 men choose hotels in a town where there are 6 hotels?

7. In how many ways can A, B, and C choose hotels in a town where there are 6 hotels, if (a) A and B refuse to stay at the same hotel, (b) they all stay at different hotels, (c) they all stay at the same hotel?

8. In how many ways can 7 books be arranged on a shelf, if 3 particular books are to be together?

9. How many signals can be made with 7 flags of different colors by arranging them on a mast (a) all together, (b) 4 at a time, (c) at least 1 at a time?

10. If the probability that A will die in 10 years is 0.2, that B will die in 10 years is 0.3, and that C will die in 10 years is 0.25, what is the probability that at the end of

10 years (a) all will be dead, (b) all will be living, (c) only two will be living, (d) at least two will be living?

11. If two dice are thrown, what is the probability of obtaining an odd number for the sum?

12. In tossing 10 coins, what is the probability of obtaining at least 8 heads?

13. A man whose batting average is $\frac{3}{10}$ will bat 4 times in a game. What is the probability that he will get 4 hits? 3 hits? 2 hits? at least 2 hits?

14. A machinist works 300 days in a year. If the probability of his meeting with an accident on any particular day is $\frac{1}{1000}$, what is the probability that he will entirely escape an accident for a year?

15. If it is known that 2 out of every 1,000 dwelling houses worth $5,000 burn annually, what is the risk assumed in insuring such a house for one year?

16. According to the American Experience Mortality Table out of 100,000 persons living at age 10 years, 91,914 are living at the age of 21 years. Each of 100 boys is now 10 years old. What is the probability that exactly 50 of them will live to be 21?

71. Meaning of mortality table.—If it were possible to trace a large number of persons, say 100,000, living at age 10 until the death of each occurred, and a record kept of the number living at each age x and the number dying between the ages x and $x + 1$, we would have a mortality table.

However, mortality tables are not constructed by observing a large number of individuals living at a certain age until the death of each, for it is evident that this method would not be practicable, but would be next to impossible, if not impossible. Mathematical methods have been devised for the construction of such tables, but the scope of this text does not permit the discussion of these methods.

Table XI is known as the American Experience Table of Mortality and is based upon the records of the Mutual Life Insurance Company of New York. It was first published in 1868 and is used for most life insurance written in the United States. It will be used in this book as a basis for all computations dealing with mortality statistics. It consists of five columns as follows: The first giving the ages running from 10 to 95, the different ages being denoted by x; the second giving the number living at the beginning of each age x and is denoted by l_x; the third giving the number dying between ages x and $x + 1$ and is denoted by d_x; the fourth giving the probability of dying in the year from age x to $x + 1$ and is denoted by q_x; and the fifth giving the probability of living a year from age x to age $x + 1$ and is denoted by p_x.

The American Experience Table, now 77 years old, is not expected to represent present-day experience. It is conservative in its estimates for insurance and thereby contributes a factor of safety to policies. Whatever added profit comes from its use is generally passed on to policy-

holders as dividends. It is now generally prescribed in the state laws as the standard for insurance evaluations.

While the American Experience Table furnishes a safe basis for insurance valuations, it is not at all suitable for the valuation of annuities. Annuities are paid to individuals during the years that they live, and computations based upon a table with mortality rates lower than the actual might easily cause a company to lose money. For the valuation of annuities, the American Experience Table is not legally prescribed so that the companies have been free to employ tables that more accurately represent the mortality they experience. The American Annuitants' Table is widely used for the valuation of annuities.

The American Experience Table and the American Annuitants' Table are " select " tables inasmuch as they show the mortality rates after the selection caused by medical examination. In 1915 the larger insurance companies of the United States cooperated in developing the American Men Mortality Table. It too is a " select " table.

Many mortality tables have been based upon the experience of the general population. Such a table includes many in poor health and others engaged in hazardous or unhealthy occupations. Since the rates of mortality in a table constructed from population records are higher than the rates of mortality of the select tables, such a table is unsuitable for life insurance valuations.

The *United States Life Tables** shows the rates of mortality among the general population in certain parts of the United States. For purposes of comparison, these tables are very enlightening, though they are inapplicable for insurance and annuity evaluations.

The following table shows the rates of mortality per 1,000 for a few ages according to the mortality tables that we have mentioned.

RATES OF MORTALITY PER 1,000

Age	American Experience	American Men	U. S. Life Table, 1910	American Annuitants'	
				Male	Female
30	8.43	4.46	6.51	4.99	4.52
35	8.95	4.78	8.04	6.00	5.27
40	9.79	5.84	9.39	7.51	6.39
45	11.16	7.94	11.52	9.78	8.07
50	13.78	11.58	14.37	13.15	10.56

* *United States Life Tables*, J. W. Glover, published by the Bureau of Census, Washington, D. C.

Exercises

1. What is the probability that a man aged 30 will live to be 65? What is the probability that the same man will die before reaching 65? What is the sum of the two probabilities?

2. Find the probability that a man aged 70 will live 10 years.

3. Suppose 100,000 lives age 10 were insured for one year by a company for $1,000 each, what would be the cost to each individual, neglecting the interest?

4. What would be the cost of $1,000 insurance for one year of an individual 30 years old, neglecting the interest, if based upon (a) the American Experience Table? (b) the American Men Table? (c) the United States Life Table?

5. Solve Exercise 4 for an individual aged 50?

72. Probabilities of life.—In Art. 71 we discussed the meaning of the mortality table and gave something concerning its history. We now derive some useful formulas based upon this table. We notice certain relations existing among the elements l_x, d_x, p_x and q_x of the table.

Since l_{x+1} denotes the number of people living at age $x + 1$ and l_x denotes the number living at age x, the probability, p_x, that a person age x will live one year is given by

$$p_x = \frac{l_{x+1}}{l_x}. \tag{12}$$

Since d_x stands for the number of people dying between the ages x and $x + 1$, the probability, q_x, that a person age x will die within a year is given by

$$q_x = \frac{d_x}{l_x}. \tag{13}$$

Since it is certain that a person age x will either live one year or die within the year, we have

$$p_x + q_x = 1. \tag{14}$$

From (12) and (13), we get

$$p_x + q_x = \frac{l_{x+1}}{l_x} + \frac{d_x}{l_x} = \frac{l_{x+1} + d_x}{l_x}.$$

Hence,

$$\frac{l_{x+1} + d_x}{l_x} = 1,$$

and

$$d_x = l_x - l_{x+1}. \tag{15}$$

The number of deaths between the ages x and $x + n$ is given by

$$l_x - l_{x+n} = d_x + d_{x+1} + \cdots + d_{x+n-1}. \tag{16}$$

When $(x + n)$ exceeds the oldest age in the table,

$$l_{x+n} = 0, \text{ and (16) becomes}$$

$$l_x = d_x + d_{x+1} + \cdots \text{ to end of table.} \tag{17}$$

The probability that a person aged x will live n years is denoted by the symbol $_n p_x$. Thus $_{15} p_{10}$ means the probability that a person aged 10 will live 15 years and is $89{,}032 \div 100{,}000$ or 0.89032.

In general,

$$_n p_x = \frac{l_{x+n}}{l_x}. \tag{18}$$

The probability that a person aged x will die within n years is denoted by $|_n q_x$. Since a person aged x will either live n years or die within that time, we have

$$_n p_x + |_n q_x = 1, \text{ or}$$

$$|_n q_x = 1 - {}_n p_x, \tag{19}$$

$$= 1 - \frac{l_{x+n}}{l_x},$$

$$|_n q_x = \frac{l_x - l_{x+n}}{l_x}. \tag{20}$$

The probability that a person aged x will die in the year after he reaches age $x + n$ is denoted by $_n | q_x$. This may be regarded as the compound event that consists of a person aged x living n years and one aged $x + n$ dying within that year. Thus we have

$$_n | q_x = {}_n p_x \cdot q_{x+n} \quad \text{(Art. 68)}$$

$$= \frac{l_{x+n}}{l_x} \cdot \frac{d_{x+n}}{l_{x+n}} = \frac{d_{x+n}}{l_x}. \tag{21}$$

Since

$$d_{x+n} = l_{x+n} - l_{x+n+1},$$

$$\frac{d_{x+n}}{l_x} = \frac{l_{x+n}}{l_x} - \frac{l_{x+n+1}}{l_x}$$

and

$$_n | q_x = {}_n p_x - {}_{n+1} p_x. \tag{22}$$

We observe from (22) that the probability that a person aged x will die in the year after reaching age $(x + n)$ is equal to the probability that a person aged x will live n years minus the probability that a person aged x will live $n + 1$ years.

The probability that a person aged x will live n years, and one aged y will die within that period is

$$_np_x \cdot \mid _nq_y = \,_np_x(1 - \,_np_y). \quad [(6), \text{ Art. } 68]. \tag{23}$$

Exercises

1. Verify from the table that $p_{15} = \dfrac{l_{16}}{l_{15}}$.

2. Verify that $q_{15} = \dfrac{d_{15}}{l_{15}}$. Does $p_{15} + q_{15} = 1$?

3. Verify that $l_{15} - l_{18} = d_{15} + d_{16} + d_{17}$.

4. Verify that $l_{90} = d_{90} + d_{91} + \ldots$ to end of table.

5. What is the probability that a person aged 20 will live 30 years and die within the next year?

6. Find the probability that a person aged 30 will live to be 65.

7. What is the probability that a person aged 25 will die within 10 years? What is the probability that he will die in the year after he reaches 35?

Problems

1. Find the probability that a man aged 40 will live to be 70.

2. What is the probability that three persons, each age 40, will all reach the age of 50? What is the probability that none will reach that age?

3. A boy 15 years old is to receive $20,000 on attaining the age of 21. Neglecting interest, what is the value of the boy's expectation?

4. Show that the probability that at least one of two lives aged x and y, respectively, will survive n years is given by the expression $_np_x + \,_np_y - \,_np_x \cdot _np_y$. Hint: We have here three mutually exclusive events.

5. A father is 40 years old and his son is 15. What is the probability that both will live 10 years? What is the probability that at least one will live 10 years?

6. What is the probability that a person aged 40 will die in the year just after reaching 60?

7. If we assume that out of 10,000 automobiles of a certain class there are 70 thefts during the year, what would it cost an insurance company to insure 1,000 such cars against theft at $700 each? What would be the premium on one such car? In this problem running expenses and interest on money are neglected.

8. Show that the probability that at least one of three lives x, y, z, respectively, will survive n years is given by the expression:

$$_np_x \cdot _np_y \cdot _np_z - (_np_x \cdot _np_y + \,_np_y \cdot _np_z + \,_np_x \cdot _np_z) + \,_np_x + \,_np_y + \,_np_z.$$

9. A man 35 years of age and his wife 33 years of age are to receive $10,000 at the end of 10 years if both are then living to receive it.   Neglecting interest, what is the value of their expectation?

10. Two persons, A and B, are 42 and 45 years of age respectively.   Find the probability (a) that both will survive 10 years, (b) that both will die within 10 years, (c) that A will survive 10 years and B will die during the time, (d) that B will survive 10 years and A will not survive.   What is the sum of the four answers?

11. A man 50 years old will receive $5,000 at the end of 10 years if he is alive.   At 4% interest, find the present value of his expectation.

12. What is the probability that a man aged 50 will live 20 years longer?

13. Given two persons of ages x and y, express the probability that:
    (a) both will live n years,
    (b) both will die within n years,
    (c) exactly one will live n years,
    (d) exactly one will die within n years.

14. To what events do the following probabilities refer?
    (a) $1 - {}_np_x \cdot {}_np_y$.
    (b) $(1 - {}_np_x)(1 - {}_np_y)$.
    (c) $1 - |{}_nq_x \cdot |{}_nq_y$.
    (d) ${}_np_x \cdot p_{x+n}$.

15. Each of 7 boys is now 10 years old.   What is the probability that (a) all seven will live to be 21 years old? (b) at least five of them will live to be 21?

16. Given 1,000 persons aged x, write expressions in terms of p_x and q_x for the following probabilities:
    (a) that exactly 10 will die within a year.
    (b) that not more than 10 will die within a year.

17. Prove: ${}_{m+n}p_x = {}_mp_x \cdot {}_np_{x+m} = {}_np_x \cdot {}_mp_{x+n}$.

18. Prove: ${}_5p_x = p_x \cdot p_{x+1} \cdot p_{x+2} \cdot p_{x+3} \cdot p_{x+4}$.

19. Translate the symbolic statement of Problem 18 into words.

20. Prove: ${}_np_x = p_x \cdot p_{x+1} \cdot p_{x+2} \ldots p_{x+n-1}$.

CHAPTER VIII

LIFE ANNUITIES

73. Pure endowments.—*A pure endowment is a sum of money payable to a person whose present age is x, at a specified future date, provided the person survives until that date.* We now find the cost of a pure endowment of $1 to be paid at the end of n years to a person whose present age is x. The symbol, $_nE_x$, will represent the cost of such an endowment.

Suppose l_x individuals, all of age x, agree to contribute equally to a fund that will assure the payment of $1 to each of the survivors at the end of n years. From the mortality table we see that out of the l_x individuals entering this agreement, l_{x+n} of them would be living at the end of n years. Consequently, the fund must contain l_{x+n} dollars at that time in order that each of the survivors receives $1. The present value of this sum is

$$v^n \cdot l_{x+n},$$

where

$$v = \frac{1}{1+i} = (1+i)^{-1}.$$

The present value of the money contributed to the fund by the l_x individuals is

$$_nE_x \cdot l_x.$$

If we equate the present value of the money contributed to the fund and the present value of the money received from the fund by the survivors, we have

$$l_x \cdot {_nE_x} = v^n \cdot l_{x+n}$$

and

$$_nE_x = \frac{v^n l_{x+n}}{l_x}. \tag{1}$$

The preceding method of derivation is known as " the mutual fund " method. The formula may also be derived by using the notion of mathematical expectation.

182

It is clear that $_nE_x$ will be the *present value of the mathematical expectation*, which is the present value of \$1 due in n years multiplied by the probability that a person aged x will live n years. Consequently

$$_nE_x = v^n \cdot {}_np_x = v^n \frac{l_{x+n}}{l_x},$$

which is the same as (1).

It should be emphasized that $_nE_x$, the present value of \$1 payable in n years to a person aged x if he lives to receive it, is dependent upon the rate of interest i and the probability that (x) will live n years.* Since these two fundamental factors v^n and $_np_x$ are generally each less than unity, $_nE_x$ is generally less than unity. Further, considering both *interest* and *survivorship*, the quantity $_nE_x$ may be looked upon as a **discount** *factor* being the discounted value of 1 due in n years to (x). Similarly, the quantity $1/_nE_x$ may be looked upon as an *accumulation factor*, being the accumulated value at the end of n years of 1 due now to (x). The line diagram shows the equivalent values.
It is obvious that the present value A, of R payable in n years to (x), is given by

$$A = R \cdot {}_nE_x. \tag{1'}$$

If the numerator and the denominator of (1) be multiplied by v^x, we get

$$\frac{v^{x+n}l_{x+n}}{v^x l_x},$$

and if we agree that the product $v^x l_x$ shall be denoted by the symbol D_x, (1) becomes

$$_nE_x = \frac{D_{x+n}}{D_x}. \tag{2}$$

D_x is one of four symbols, called commutation symbols, that are used to facilitate insurance computations (see Table XII). This table is based on the American Experience Table of Mortality and a $3\frac{1}{2}\%$ interest rate is used. There are other commutation tables based upon different tables of mortality and different rates of interest.

* We shall frequently use the symbol (x) to mean "a person aged x" or "a life aged x."

It will be observed as the theory develops that we rarely use the values given in the mortality table except to compute the values of the commutation symbols.

Unless otherwise specified, all computations in the numerical exercises will be based upon the American Experience Table of Mortality with $3\frac{1}{2}$ per cent per annum as the interest rate.

Exercises

1. Find the present value (cost) of a pure endowment of $5,000, due in 20 years and purchased at age 30, interest at $3\frac{1}{2}\%$.

Solution. Here, $x = 30$, $n = 20$, and

$$_{20}E_{30} = \frac{D_{50}}{D_{30}} = \frac{12498.6}{30440.8} = 0.410587. \quad \text{[Formula (2) and Table XII]}$$

Hence, $A = (5,000.00) {}_{20}E_{30} = 5,000 (0.410587)$

$$= \$2,052.94.$$

2. Solve Exercise 1, with the rate of interest 3%.

3. An heir, aged 14, is to receive $30,000 when he becomes 21. What is the present value of his expectation on a 4% basis?

4. Find the cost of a pure endowment of $2,000, due in 10 years and purchased at age 35, interest at $3\frac{1}{2}\%$.

5. What pure endowment due at the end of 20 years could a person aged 45 purchase for $5,000? Assume $3\frac{1}{2}\%$ interest.

6. Solve Exercise 5, assuming 4% interest.

7. A boy aged 12 is to receive $10,000 upon attaining age 21. Find the present value of the inheritance on a 4% basis.

8. A man aged 30 has $10,000 that he wishes to invest with an insurance company that operates on a $3\frac{1}{2}\%$ basis. He wishes the endowment to be payable to him when he attains the age of 50 years. What would be the amount of the investment at that time if he agrees to forfeit all rights in the event of death before he reaches age 50?

9. Two payments of $5,000 each are to be received at the ends of 5 and 10 years respectively. Find the present value at $3\frac{1}{2}\%$
      (a) if they are certain to be received;
      (b) if they are to be received only if (25) is alive to receive them.

10. What pure endowment payable at age 65 could a man age 25 purchase with $1,000 cash?

11. To what formula would the formula for $_{n}E_{x}$ reduce if (x) were sure to survive n years? To what would it reduce if money were unproductive?

12. Show that
      (a) $_{m+n}E_{x} = {}_{m}E_{x} \cdot {}_{n}E_{x+m}$;
      (b) $_{n}E_{x} = {}_{1}E_{x} \cdot {}_{1}E_{x+1} \cdot {}_{1}E_{x+2} \ldots \ldots {}_{1}E_{x+n-1}$.

74. Whole life annuity.—*A whole life annuity is a succession of equal periodic payments which continue during the entire life of the individual concerned.* It is evident that the cost of such an annuity depends upon the probability of living as well as upon the rate of interest.

The terms *payment interval, annual rent, term, ordinary, due, deferred,* have similar meanings in life annuities that they have in annuities certain. Unless otherwise specified, the words *life annuity* will be taken to mean *whole life annuity.*

75. Present value (cost) of a life annuity.—We now propose to find the present value of an ordinary life annuity of \$1 per annum payable to an individual, now aged x. The symbol, a_x, is used to denote the cost of such an annuity. We see that the present value of this annuity is merely the sum of the present values of pure endowments, payable at the ends of one, two, three, and so on, years. Consequently,

$$a_x = {_1}E_x + {_2}E_x + {_3}E_x + \ldots \text{ to end of table}$$

$$= \frac{D_{x+1}}{D_x} + \frac{D_{x+2}}{D_x} + \frac{D_{x+3}}{D_x} + \ldots \text{ to end of table}$$

$$= \frac{D_{x+1} + D_{x+2} + D_{x+3} + \ldots \text{ to end of table}}{D_x}$$

$$a_x = \frac{N_{x+1}}{D_x} \tag{3}$$

where

$$N_x = D_x + D_{x+1} + D_{x+2} + \ldots \text{ to end of table} \tag{4}$$

[See Table XII]

The symbol N_x (called " double bar N ") as defined above is that generally adopted in America. In actuarial parlance, it is frequently called the *American N.* The English textbooks use the single bar N which is defined by the equation

$$N_x = D_{x+1} + D_{x+2} + D_{x+3} + \ldots \text{ to end of table.}$$

In this book we shall use the " double bar " American N.

Exercises

1. What is the cost of a life annuity of \$600 per annum for a person aged 30, interest at $3\frac{1}{2}\%$?

Solution. From (3), Art. 75, we have

$$a_{30} = \frac{N_{31}}{D_{30}} = \frac{566362.9}{30440.8} = 18.60538. \qquad \text{[Table XII]}$$

Hence, the annuity has a cost (present value) of

$$600(18.60538) = \$11,163.23.$$

2. Find the present value of a life annuity to a person aged 60, the annual payment to be $1,200.

3. What annual life income could a person aged 50 purchase with $10,000.

4. Derive the formula for a_x by the *mutual fund method*.

5. Show that $a_x = vp_x(1 + a_{x+1})$
    (a) algebraically,
    (b) by verbal interpretation or direct reasoning using the following line diagram:

$$
\begin{array}{ccccccc}
1 & 1 & 1 & \cdots\cdots\cdots & 1 & 1 & \text{year of death} \\
\end{array}
$$
$$
\text{Age } x \quad x+1 \quad x+2 \quad x+3 \quad \cdots\cdots\cdots
$$
6. A man aged 60 is promised a pension of $600 at the end of each year as long as he lives. What is the present value of the pension?

7. The beneficiary, age 50, of a life insurance policy may receive $25,000 cash or an ordinary life annuity of annual rent R. If she chooses the annuity, find R.

76. Life annuity due.—When the first payment under an annuity is made immediately, we have what is called an annuity due. The present value of an annuity due of $1 per annum to a person aged x is denoted by a_x. An annuity due differs from an ordinary annuity (Art. 75) only by an immediate payment. Consequently, we have*

$$\mathbf{a}_x = 1 + a_x \tag{5}$$

$$= 1 + \frac{N_{x+1}}{D_x} = \frac{D_x + N_{x+1}}{D_x}$$

$$= \frac{D_x + D_{x+1} + D_{x+2} + \ldots \text{ to end of table}}{D_x}$$

$$\mathbf{a}_x = \frac{N_x}{D_x}. \tag{6}$$

77. Deferred life annuity.—When the first payment under an annuity is not made until some specified future date, and then only in case the individual, now aged x, is still living, we have what is called a deferred annuity. Since the first payment under an ordinary annuity is made at the end of one year, an annuity providing for first payment at the end

* Values of a_x and $\mathbf{a}_x$ may be found in Table XII.

of n years is said to be deferred $n - 1$ years. Then in an annuity deferred n years the first payment would not be made until the end of $n + 1$ years.

These payments are illustrated by the diagram
The present value of an annuity of \$1 per annum, deferred n years, payable to an individual now aged x, if he is then living is denoted by the symbol, $_n|a_x$. It is evident that the present value of such an annuity is merely the sum of the present values of pure endowments payable at the end of $n + 1$, $n + 2$, $n + 3$, and so on, years so long as the individual survives.

Consequently,

$$_n|a_x = {}_{n+1}E_x + {}_{n+2}E_x + {}_{n+3}E_x + \dots \text{ to end of table}$$

$$= \frac{D_{x+n+1}}{D_x} + \frac{D_{x+n+2}}{D_x} + \dots$$

$$_n|a_x = \frac{N_{x+n+1}}{D_x}. \tag{7}$$

Let $_n|a_x$ denote the present value of a *deferred whole life annuity due*, that is, a succession of \$1 payments to be made at the ends of n years, $n + 1$ years, and so on as long as (x) survives. These payments are illustrated by the following line diagram:
The value at age $x + n$ of these payments is a_{x+n}, and the value at age x, the present value, is $a_{x+n} \cdot {}_nE_x$. Consequently

$$_n|\ddot{a}_x = a_{x+n} \cdot {}_nE_x = \frac{N_{x+n}}{D_{x+n}} \cdot \frac{D_{x+n}}{D_x} = \frac{N_{x+n}}{D_x^-}. \tag{8}$$

78. Temporary life annuity.—When the payments under a life annuity stop after a certain time although the individual be still living, we have what is called a *temporary annuity*. Such an annuity of \$1 per annum which ceases after n years is denoted by the symbol, $a_{x\overline{n}|}$. It is clear that the present value of a temporary annuity is equal to the sum of present

values of pure endowments of \$1 payable at the ends of 1, 2, 3, . . ., n years.
Thus,

$$a_{x\overline{n}|} = {}_1E_x + {}_2E_x + \ldots + {}_nE_x$$

$$= \frac{D_{x+1} + D_{x+2} + \ldots + D_{x+n}}{D_x}$$

$$= \frac{D_{x+1} + D_{x+2} + \ldots \text{ to end of table}}{D_x} -$$

$$\frac{D_{x+n+1} + D_{x+n+2} + \ldots \text{ to end of table}}{D_x}$$

$$\boldsymbol{a_{x\,\overline{n}|}} = \frac{N_{x+1} - N_{x+n+1}}{D_x}. \tag{9}$$

If the first of the n payments be made immediately and the last payment be made at the end of $n - 1$ years, we then have a temporary annuity due.   Letting $a_{x\,\overline{n}|}$ represent the present value of such an annuity we get

$$a_{x\overline{n}|} = 1 + a_{x\overline{n-1}|}$$

$$= 1 + \frac{D_{x+1} + D_{x+2} + \ldots + D_{x+n-1}}{D_x}$$

$$= \frac{D_x + D_{x+1} + D_{x+2} + \ldots + D_{x+n-1}}{D_x}$$

$$\boldsymbol{a_{x\,\overline{n}|}} = \frac{N_x - N_{x+n}}{D_x}. \tag{10}$$

Exercises

1. An insurance company accepts from a man, aged 30, \$85.89 per annum in advance for 10 years if living as payment for insurance.   What would be the equivalent single premium based upon the American Experience Table of Mortality and $3\frac{1}{2}\%$ interest?

2. A will provides that a son is to receive a life annuity of \$1,500 a year, the first payment to be made when the son attains the age of 60.   What is the value of the son's share when he is 40 years old?

3. A man aged 50 pays \$10,000 for a life annuity whose first payment is to be made when he is 60 years old.   What will be his annual income beginning at age 60?

4. A will provides that a son who is now 25 years old is to receive \$1,200 at the end of one year, and a like amount at the end of each year until 10 payments in all have been made.   If each payment is contingent upon the son being alive, what is the value of his estate at age 25?

5. Make $n = 0$ in formula (7) and show that it reduces to formula (3). What does this mean?

6. Show that $a_x = a_{x\,\overline{n}|} + {}_n|a_x$
  (a) algebraically,
  (b) by direct reasoning with the aid of an appropriate line diagram.

7. Derive formulas (7) and (9) by the mutual fund method.

8. Derive formula (8) by finding the sum of appropriate pure endowments.

9. Draw line diagrams to illustrate the meaning of the following symbols:

$$a_{50}, \ a_{25\,\overline{20}|}, \ a_{25\,\overline{15}|}, \ {}_{10}|a_{25}.$$

10. Prove $a_{x\,\overline{m+n}|} = a_{x\,\overline{m}|} + {}_mE_x \cdot a_{x+m\,\overline{n}|}$
  (a) algebraically,
  (b) by direct reasoning.

11 Prove the following identities:
  (a) $a_{x\,\overline{n}|} = 1 + a_{x\,\overline{n-1}|}$,
  (b) $a_x = a_{x\,\overline{n}|} + {}_n|a_x$.

12. A beneficiary, age 50, of a life insurance policy may receive \$25,000 cash or a temporary life annuity due for 15 years. If she chooses the annuity, find its amount.

79. Forborne temporary life annuity due.

—An individual aged x may be entitled to a life annuity due of \$1 per annum, but forbears to draw it. Instead he requests that the unpaid installments be allowed to accumulate as pure endowments until he is aged $x + n$. Such an annuity is known as a *forborne temporary life annuity due.*

The problem here is to find the value of such an annuity, taken at age x, to the person at age $x + n$ if he is still alive. *This value is equal to the n-year pure endowment that the present value of a temporary life annuity due of \$1 per annum will buy.* The present value of a temporary life annuity due of \$1 per annum is

$$\frac{N_x - N_{x+n}}{D_x} \qquad [(10) \text{ Art. } 78]$$

Since $\dfrac{D_{x+n}}{D_x}$ [(2) Art. 73] will buy an n-year pure endowment of \$1, \$1 will buy an n-year pure endowment of $\dfrac{D_x}{D_{x+n}}$, and consequently $\dfrac{N_x - N_{x+n}}{D_x}$ will buy an n-year pure endowment of *

$$_nu_x = \frac{N_x - N_{x+n}}{D_x} \cdot \frac{D_x}{D_{x+n}} = \frac{N_x - N_{x+n}}{D_{x+n}}. \qquad (11)$$

---

* The symbol ${}_nu_x$ is customarily used to stand for the amount at age $x + n$ of the forborne temporary life annuity due of \$1 per annum. It is one of the most useful functions for the actuary.

It follows that R per annum payable in advance for n years as a temporary life annuity will buy an n-year pure endowment of

$$S = R \cdot {}_n u_x = R \frac{N_x - N_{x+n}}{D_{x+n}}. \tag{12}$$

Since $\dfrac{N_{x+n}}{D_{x+n}}$ is the cost of a life annuity due of \$1 per annum for an individual aged $x + n$, \$1 at age $x + n$ will buy a life annuity due of $\dfrac{D_{x+n}}{N_{x+n}}$ per annum, and $\dfrac{N_x - N_{x+n}}{D_{x+n}}$ at age $x + n$ will buy a life annuity due of

$$\frac{N_x - N_{x+n}}{D_{x+n}} \cdot \frac{D_{x+n}}{N_{x+n}} = \frac{N_x - N_{x+n}}{N_{x+n}}.$$

Hence, it follows that with \$1 per annum payable in advance by an individual now aged x, a life annuity due of $\dfrac{N_x - N_{x+n}}{N_{x+n}}$ per annum, beginning at age $x + n$, may be bought.

Then R dollars per annum payable in advance as a temporary life annuity by an individual now aged x, will buy a life annuity due of

$$R \frac{N_x - N_{x+n}}{N_{x+n}} \tag{13}$$

beginning at age $x + n$.

It may be shown that

$$K \frac{N_{x+n}}{N_x - N_{x+n}} \tag{14}$$

per annum payable in advance for n years by an individual now aged x, will buy him a life annuity due of K dollars per annum beginning when he is aged $x + n$. Here, an individual aged x is buying a regular life annuity of K dollars per annum, deferred $n - 1$ years, by paying $K \dfrac{N_{x+n}}{N_x - N_{x+n}}$ dollars annually in advance.

80. Summary of formulas of life annuities. Examples.

$$R = \text{the annual payment,}$$

$$(x) = \text{the person of age } x.$$

Pure Endowment: $\qquad A = R(_nE_x) = R\dfrac{D_{x+n}}{D_x}.$ $\qquad$ (1')

Whole life annuity: $\qquad A = R(a_x) = R\dfrac{N_{x+1}}{D_x}.$ $\qquad$ (3')

Whole life annuity due: $\qquad A = R(\mathrm{a}_x) = R\dfrac{N_x}{D_x}.$ $\qquad$ (6')

Deferred life annuity: $\qquad A = R(_n\,|\,a_x) = R\dfrac{N_{x+n+1}}{D_x}.$ $\qquad$ (7')

Deferred life annuity due: $\quad A = R(_n\,|\,\mathrm{a}_x) = R\dfrac{N_{x+n}}{D_x}.$ $\qquad$ (8')

Temporary life annuity: $\quad A = R(a_{x\,\overline{n}|}) = R\dfrac{N_{x+1} - N_{x+n+1}}{D_x}.$ $\qquad$ (9')

Temporary life annuity due: $A = R(\mathrm{a}_{x\,\overline{n}|}) = R\dfrac{N_x - N_{x+n}}{D_x}.$ $\qquad$ (10')

Forborne temporary life annuity due: $\qquad S = R(_nu_x) = R\dfrac{N_x - N_{x+n}}{D_{x+n}}.$ $\qquad$ (12)

Example 1. A man aged 30 pays an insurance company \$1,000 annually, in advance, for 20 years for the purchase of a pure endowment. What will be the amount of the endowment if he lives to claim it?

Solution. The annual payments constitute a forborne temporary life annuity due in which $x = 30$, $n = 20$, $R = 1,000$. Using (12), we find

$$S = 1,000\,\frac{N_{30} - N_{50}}{D_{50}} = 1,000\,\frac{596,804 - 181,663}{12,498.6}$$

$$= \$33,215.00.$$

Example 2. A man aged 30 pays an insurance company \$100 annually, in advance, for 35 years to purchase a life annuity, the first payment to be made when the annuitant reaches age 65. What is the annual rent of his annuity?

Solution. Consider the line diagram.

Age: 30, 31, 32 ..... 64, 65, 66 with 100 payments from 30 to 64, and R payments at 65, 66 ...
We shall choose age 65 as the focal time.

The value at age 65 of the payments is that of a forborne temporary life annuity due with $x = 30$, $n = 35$, $R = 100$. Using (12) we find

$$S = 100 \frac{N_{30} - N_{65}}{D_{65}}.$$

The value of the benefit is that of a life annuity due on a life aged 65. Using (6'), the value of the benefit is

$$A = R \frac{N_{65}}{D_{65}}.$$

Therefore,

$$R \cdot \frac{N_{65}}{D_{65}} = 100 \frac{N_{30} - N_{65}}{D_{65}},$$

and

$$R = 100 \frac{N_{30} - N_{65}}{N_{65}} = 100 \frac{596{,}804 - 48{,}616.4}{48{,}616.4}$$

$$R = \$1{,}127.58.$$

Exercises

1. In the settlement of an estate a man, aged 30, is to receive $1,000 and a like amount at the end of each year. However, he requests that this annuity be forborne until he reaches the age of 60. What will be the amount of these forborne payments at that time on a $3\frac{1}{2}\%$ interest basis?

2. A young man, aged 25, pays $300 per annum in advance to accumulate as a pure endowment until age 60. What will be the amount of his endowment at age 60 on a $3\frac{1}{2}\%$ basis? Suppose that at age 60 he does not take the amount of his endowment in cash, but instead purchases a life annuity due. What would be his annual income on a $3\frac{1}{2}\%$ basis?

3. An individual now aged 30 desires to make provisions for his retirement at age 60. How much per annum, in advance, must he pay for the next 30 years to guarantee a life annuity due of $3,000 per annum beginning at age 60?

4. A person whose present age is 25 desires to have a life income of $1,500 beginning at age 60. How much must he invest annually in advance for the next 35 years to guarantee his desired income?

5. A man aged 50 pays an insurance company $20,000 for a contract to pay him a life annuity with the first payment to be made at age 65. Find the annual payment of the annuity.

6. A corporation has promised to pay an employee, now aged 50, a pension of $1,000 at the end of each year, starting with a payment on his 65th birthday. What is the present value of this expectancy?

7. A certain insurance policy on a life aged 30 calls for premiums of \$100 at the beginning of each year as long as he lives. Find the present value of the premiums.

8. A certain insurance policy on a life aged 30 calls for premiums of \$100 at the beginning of each year for 20 years. Find the present value of the premiums.

9. A man aged 30 wishes a life annuity of \$1,000 a year, the first payment to be made when he is 65 years old. To provide for this, he will pay R per year in advance for the next 20 years. Find R.

10. A man aged 55 is to receive a life annuity of \$1,000 a year, the first payment to be made immediately. He wishes to postpone the annuity so that the first payment will occur on his 65th birthday. What will be his annual income?

11. A certain life insurance policy matures when the policy-holder is aged 50 and gives him an option of \$10,000 in cash or a succession of equal payments for 10 years certain and as long thereafter as he may live. Should he die during the first ten years, the payments are to be continued to his heirs until a total of ten have been made. Find the annual payment under the optional plan.

Hint. The equation of value is $R(a_{\overline{10}|} + {}_{10}|a_{50}) = 10,000$.

12. Show by direct reasoning that the annual premium for n years, beginning at age x, for an annuity of 1 per year, beginning at age $x + n$, is given by $a_{x+n}/{}_nu_x$.

13. A boy of age 15 is left an estate of \$50,000 which is invested at 4% effective. He is to receive the income annually, if living, and at age 25 he is to receive the principal, if living. Find the present value of the inheritance.

14. How much must an individual now aged x invest at the beginning of each year for n years, if living, to secure an annuity of R dollars per annum payable for t years certain and as long thereafter as he may live?

Hint. Focalize at age $x + n$. Let y be the annual payment. The equation of value is

$$y({}_nu_x) = R(a_{\overline{t}|} + {}_t|a_{x+n}).$$

15. A person whose present age is 25 desires to have an income of \$1,000 a year for 10 years certain and as long thereafter as he may live, first payment at age 60. How much must he invest annually in advance for the next 35 years to guarantee this income?

81. Annuities payable m times a year.—Optional provisions are usually made in annuity contracts so that the periodical payments may be made m times a year. The symbol $a_x^{(m)}$ is used to denote the present value of a life annuity of \$1/m payable m times a year, and $a_x^{(m)}$ is used to denote the present value of a life annuity due of \$1/m payable m times a year. Theoretically, it follows from Art. 73, that

$$a_x^{(m)} = \frac{1}{m}\left[{}_{\frac{1}{m}}E_x + {}_{\frac{2}{m}}E_x + {}_{\frac{3}{m}}E_x + \cdots\right]. \tag{15}$$

It is apparent that (15) would involve considerable computation and besides the mortality table does not take into consideration fractional

parts of years. However, we may derive an approximate formula for $a_x^{(m)}$ which is accurate enough for most purposes.

The deferred annuity due may be written

$$_0|\mathbf{a}_x = (1 + a_x) - 0$$

and

$$_1|\mathbf{a}_x = (1 + a_x) - 1.$$

By simple proportion,

$$_{\frac{1}{m}}|\mathbf{a}_x = (1 + a_x) - \frac{1}{m} = a_x + \frac{m-1}{m}$$

and, in general,

$$_{\frac{k}{m}}|\mathbf{a}_x = (1 + a_x) - \frac{k}{m} = a_x + \frac{m-k}{m}.$$

Assume that we have m such annuities, where the first payments are to be made at the ends of $\dfrac{1}{m}, \dfrac{2}{m}, \dfrac{3}{m}, \cdots, \dfrac{m}{m}$ of a year, respectively. Together they will provide \$1 at the end of each $\dfrac{1}{m}$-th of a year. Hence,

$$ma_x^{(m)} = \left(a_x + \frac{m-1}{m}\right) + \left(a_x + \frac{m-2}{m}\right) + \cdots + \left(a_x + \frac{m-k}{m}\right)$$
$$+ \cdots + \left(a_x + \frac{m-m}{m}\right).$$

The right-hand side of the above equation is the sum of an arithmetical progression with a common difference of $-\dfrac{1}{m}$. Consequently

$$ma_x^{(m)} = ma_x + \frac{m(m-1)}{2m},$$

and

$$a_x^{(m)} = a_x + \frac{(m-1)}{2m} = \frac{N_{x+1}}{D_x} + \frac{(m-1)}{2m}. \tag{16}$$

If the first payment is made at once, we have

$$\mathbf{a}_x^{(m)} = \frac{1}{m} + a_x^{(m)} = \frac{1}{m} + a_x + \frac{m-1}{2m}$$

$$\mathbf{a}_x^{(m)} = a_x + \frac{m+1}{2m}. \tag{17}$$

The student should observe the difference between (16) and (17).

If we let $_n \mid a_x^{(m)}$ stand for the present value of an annuity of \$1 deferred n years and payable in m installments a year, and reason as in Art. 73, we get

$$_n \mid a_x^{(m)} = v^n \cdot _np_x \cdot a_{x+n}^{(m)} = v^n \frac{l_{x+n}}{l_x} \cdot a_{x+n}^{(m)}$$

$$= \frac{D_{x+n}}{D_x} \cdot a_{x+n}^{(m)}$$

$$_n \mid a_x^{(m)} = \frac{D_{x+n}}{D_x} \left(a_{x+n} + \frac{m-1}{2m} \right). \tag{18}$$

Also, if we let $a_{x\,\overline{n}|}^{(m)}$ stand for the present value of a temporary life annuity of \$1 payable in m installments a year and consider that a life annuity is made up of a temporary annuity and a deferred annuity, we get

$$a_x^{(m)} = a_{x\,\overline{n}|}^{(m)} + _n \mid a_x^{(m)}$$

and

$$a_{x\,\overline{n}|}^{(m)} = a_x^{(m)} - _n \mid a_x^{(m)} \tag{19}$$

$$a_{x\,\overline{n}|}^{(m)} = a_x + \frac{m-1}{2m} - \frac{D_{x+n}}{D_x} \left(a_{x+n} + \frac{m-1}{2m} \right). \tag{20}$$

Exercises

1. What is the present value of a life annuity of \$100 payable at the end of every month to a person aged 30?

Solution. Here, $x = 30$ and $m = 12$. From (16), Art. 81, we have

$$a_{30}^{(12)} = a_{30} + \tfrac{11}{24}.$$

$$a_{30} = \frac{N_{31}}{D_{30}} = \frac{566{,}363}{30{,}440.8} = 18.6054.$$

and

$$(1{,}200)\, a_{30}^{(12)} = 1{,}200\,(18.6054 + 0.4583) = \$22{,}876.44.$$

2. Solve Exercise 1, with the annuity payable quarterly.

3. Find the cost of a temporary life annuity of \$600 per annum, payable in 12 monthly installments for 20 years, first payment due one month hence. Assume age 30.

4. Solve Exercise 3, with the annuity paid at the rate of \$300 at the end of every six months.

5. Find the cost of a life annuity due of \$1,000 per annum, payable in quarterly installments, for a person aged 40.

Problems

1. Show that the present value of an annuity of $1, payable for n years certain and so long thereafter as the individual, now aged x, survives (first payment due one year hence) is given by

$$a_{\overline{n}|} + {}_n|\, a_x.$$

Also show that the present value of an annuity due of $1, payable for n years certain and so long as an individual, now aged x, may live, is given by

$$1 + a_{\overline{n-1}|} + {}_{n-1}|\, a_x.$$

2. What is the value of an annuity of $1,000 per annum payable at the end of each year for 10 years certain and so long thereafter as an individual, now aged 60, survives?

3. According to the terms of a will a person aged 30 is to receive a life income of $6,000 per annum, first payment at once. An inheritance tax of 4% on the present value of the income must be paid at once. Find the present value of the income and the amount of the tax.

4. What would be the present value of the income of **Problem 3 if payments of** $500 a month were made at the beginning of each month?

5. What would be the value of the annuity in Problem 2, if the payments were made at the end of each year for 20 years certain and for life thereafter?

6. A man carrying a $20,000 life insurance policy arranges it so that the proceeds at his death shall be payable to his wife in annual installments for 10 years certain, first payment upon due proof of death. What would be the annual installment, assuming $3\frac{1}{2}\%$ interest?

7. What would be the amount of the annual installments of Problem 6, if payable for 10 years certain and so long thereafter as the beneficiary shall survive, assuming that the beneficiary was 55 years of age at the death of the insured?

8. What would be the amount of the annual installments in the above problem, if payments were to be made throughout the life of the beneficiary?

9. What would be the amount of the annual installments in Problem 8, if payable for 10 years, each payment contingent upon the beneficiary being alive?

10. Assume that the proceeds in Problem 9 are to be paid monthly. What would be the monthly installment?

11. Show that

$$\mathrm{a}_{x\,\overline{n}|}^{(m)} = \mathrm{a}_x - \frac{m-1}{2m} - \frac{D_{x+n}}{D_x}\left[\frac{N_{x+n}}{D_{x+n}} - \frac{m-1}{2m}\right],$$

where $\mathrm{a}_{x\,\overline{n}|}^{(m)}$ stands for the present value of a temporary annuity due of $1 payable in m installments per annum.

12. A suit for damages due to the accidental death of a railroad employee 42 years old and earning $175 a month was settled on the basis of three-fourths of the present value of the expected wages of $175 a month during his after lifetime. What was the amount of the damages?

13. By the terms of a will, a son is bequeathed an estate of $100,000 with the provision that he must pay his mother who is 60 years of age $200 monthly as long as she lives? What is the value of the son's inheritance?

14. Prove: $_{m+n}u_x = {_m}u_x \cdot \dfrac{1}{_nE_{x+m}} + {_n}u_{x+m}.$

15. Prove:

    (a) $a_{x+1} = {_1}u_x(a_x - 1),$

    (b) $a_x = ({_n}u_x + a_{x+n})_nE_x,$

    (c) $a_{x\,\overline{n|}}^{(m)} = a_{x\,\overline{n|}} + \dfrac{m-1}{2m}\,(1 - {_n}E_x),$

    (d) $\mathrm{a}_{x\,\overline{n|}}^{(m)} = \mathrm{a}_{x\,\overline{n|}} - \dfrac{m-1}{2m}\,(1 - {_n}E_x).$

16. A woman aged 30 offers \$20,000 to a benevolent organization if it will pay her 5% interest thereon at the beginning of each year for the remainder of her life. If the institution can purchase the desired annuity for her from an insurance company which operates on a $3\frac{1}{2}\%$ basis, will it pay to accept the offer?

17. A man aged 65 is to receive a life annuity of \$1,000 a year, the first payment being due immediately. He desires to postpone the annuity so that the first annual payment will occur when he is aged 70. What will be the annual income from the new annuity?

18. A man aged 55 is entitled to a life annuity of \$1,000. He agrees to use it to purchase a 10-year pure endowment. What is the amount of the pure endowment?

19. A young man aged 25 is to receive as an inheritance a life income of \$100 a month, first payment immediately. An inheritance tax of 5% on the present value is levied. Find the amount of the tax.

20. A man aged 60 is granted a pension of \$1,000 a year for 10 years, first payment at once, and \$500 a year thereafter for the rest of his life. If all payments are contingent on his survival, find their present value.

21. Show that the present value of a perpetuity of \$1 per year, the first payment to be made at the end of the year in which (x) dies, is $1/i - a_x$. See Art. 37.

CHAPTER IX

LIFE INSURANCE, NET PREMIUMS (SINGLE AND ANNUAL)

82. Definitions.—A thorough mathematical treatment of life insurance involves many very complex problems. However, there are a few principles that are fundamental and it is these with which we wish to deal in this chapter. Life insurance is fundamentally sound only when a large group of individuals is considered. Each person contributes to a general fund from which the losses sustained by individuals of the group are paid. The organization that takes care of this fund and settles the claims for all losses is known as an *insurance company*. The deposit made to this fund by the individuals is called a *premium*. Since the payment of this premium by the individual insures a certain sum or *benefit* at his death,* he is spoken of as the *insured* and the person to whom the benefit is paid at the death of the insured is called the *beneficiary*. The agreement made between the insured and the company is called a *policy* and the insured is sometimes spoken of as the *policy-holder*.

The fundamental problem of life insurance is the determination of the *premium* that is to be charged the policy-holder in return for the *benefits* promised him by the policy. It is clear that the premium will depend upon the probability of dying and also upon the rate of interest on funds left with the company. That is, the premium requires a mortality table and an assumed rate of interest. The premium based upon these two items is called the *net premium*.

The American Experience Table of Mortality is the standard, in the United States, for the calculation of net premiums and for the valuation of policies. We shall in all our problems on life insurance assume this table and interest at $3\frac{1}{2}\%$. In computing the net premiums, we shall also assume that the benefits under the policy are paid at the ends of the years in which they fall due.

The insurance company has many expenses, in connection with the securing of policy-holders, such as advertising, commissions, salaries, office

---

* Certain insurance agreements specify the payment of an indemnity to the individual himself in case he is disabled by either accident or sickness. This is known as *accident and health insurance*, but we shall not attempt to treat it in this book.

supplies, et cetera, and consequently, must make a charge in addition to the net premium. The net premium plus this additional charge is called the *gross* or *office premium*. In this chapter we shall discuss only net premiums and leave gross premiums for another chapter. The premium may be *single*, or it may be paid annually, and this annual premium may sometimes be paid in semi-annual, quarterly or even monthly installments. All premiums are paid in advance.

83. Whole life policy.—*A whole life policy is one wherein the benefit is payable at death and at death only.* The net single premium on a whole life policy is the present value of this benefit. The symbol A_x will stand for the net single premium of a benefit of \$1 on (x).

Let us assume that each of l_x persons all of age x, buys a whole life policy of \$1. During the first year there will be d_x deaths, and consequently, at the end * of the first year the company will pay d_x dollars in benefits, and the present value of these benefits will be vd_x. There will be d_{x+1} deaths during the second year and the present value of the death benefits paid will be v^2d_{x+1}, and so on. The sum of the present values of all future benefits will be given by the expression

$$vd_x + v^2d_{x+1} + v^3d_{x+2} + \cdots \text{ to end of table.}$$

Since l_x persons buy benefits of \$1 each, the present value of the total premiums paid to the company is $l_x \cdot A_x$.

Equating the present value of the total premiums paid and the present value of all future benefits, we have

$$l_x \cdot A_x = vd_x + v^2d_{x+1} + v^3d_{x+2} + \cdots \text{ to end of table.}$$

Solving the above equation for A_x, we get

$$A_x = \frac{vd_x + v^2d_{x+1} + v^3d_{x+2} + \cdots \text{ to end of table}}{l_x}. \tag{1}$$

If both the numerator and the denominator of (1) be multiplied by v^x, we get

$$A_x = \frac{v^{x+1}d_x + v^{x+2}d_{x+1} + \cdots \text{ to end of table}}{v^x l_x}$$

$$= \frac{C_x + C_{x+1} + C_{x+2} + \cdots \text{ to end of table}}{D_x}$$

$$A_x = \frac{M_x}{D_x} \tag{2}$$

* We assume that the death benefit is paid at the end of the year of death.

where

$$C_x = v^{x+1}d_x, \quad C_{x+1} = v^{x+2}d_{x+1}, \text{ and so on,}$$

and

$$M_x = C_x + C_{x+1} + C_{x+2} + \cdots \text{ to end of table.}$$

The expressions C_x and M_x are two new commutation symbols that are needed in this chapter. They are tabulated in Table XII.

If in (1) d_x be replaced by its equal $l_x - l_{x+1}$, and so on, we get

$$A_x = \frac{v(l_x - l_{x+1}) + v^2(l_{x+1} - l_{x+2}) + \cdots}{l_x}$$

$$= \frac{(vl_x + v^2l_{x+1} + \cdots)}{l_x} - \frac{(vl_{x+1} + v^2l_{x+2} + \cdots)}{l_x}$$

$$= v\left(1 + \frac{vl_{x+1} + v^2l_{x+2} + \cdots}{l_x}\right) - \left(\frac{vl_{x+1} + v^2l_{x+2} + \cdots}{l_x}\right)$$

$$= v(1 + {}_1E_x + {}_2E_x + \cdots) - ({}_1E_x + {}_2E_x + \cdots)$$

$$A_x = v(1 + a_x) - a_x. \quad \text{Art. 75.} \tag{3}$$

If (x) agrees to pay for the insurance of \$1 on his life in one installment in advance, the amount he must pay is A_x. Most people do not desire, or cannot afford, to purchase their insurance by a single payment, but prefer to distribute the cost throughout life or for a limited period. For the convenience of the insured, the policies commonly issued provide for the payment of premiums in equal annual payments. The corresponding net premiums are called *net level annual premiums.*

A common plan is to pay a level premium throughout the life of the insured. When this is the case the policy is called an *ordinary life insurance policy.*

We will denote the net annual premium of an ordinary life policy of \$1 by the symbol P_x. The payment of P_x, at the beginning of each year, for life forms a life annuity due and the present value of this annuity must be equivalent to the net single premium. Thus we have,

$$P_x \cdot a_x = A_x. \tag{4}$$

Solving for P_x, we get

$$P_x = \frac{A_x}{a_x} = \frac{M_x}{N_x}, \tag{5}$$

since

$$A_x = \frac{M_x}{D_x},$$

and

$$a_x = \frac{N_x}{D_x}. \quad [(6) \text{ Art. 76}]$$

Another common plan—probably the plan that occurs most frequently—is to pay for the insurance by paying the level premium for a limited number of years. When this is the case, the policy is called a *limited payment life policy*. The standard forms of limited payment policies are usually for ten, fifteen, twenty, or thirty annual payments, but other forms may be written.

Let us consider the *n*-payment life policy.

It is evident that the *n* annual premiums on the limited payment life policy form a temporary life annuity due. It is also clear that the present value of this annuity is equivalent to the net single premium A_x. Hence, if the net annual premium for a benefit of $1 be denoted by $_nP_x$, we may write

$$_nP_x \cdot a_{x\,\overline{n}|} = A_x.$$

Solving for $_nP_x$ and substituting for $a_{x\,\overline{n}|}$ and A_x, we have

$$_nP_x = \frac{M_x}{N_x - N_{x+n}}. \tag{6}$$

Exercises

1. Use (1) Art. 83 to find the net single premium for a whole life policy to insure a person aged 91 for $2,000.

2. Find the net single premium for a whole life policy of $10,000 on a life aged 30.

3. Find the annual premium for an ordinary life policy of $10,000 on a life aged 30.

4. Find the net annual premium on a 20-payment life policy of $5,000 for a person aged 30.

5. Assuming that each of l_x persons, all of age x, buys an ordinary life policy of $1, show from fundamental principles that

$$P_x(l_x + vl_{x+1} + v^2l_{x+2} + \cdots) = (vd_x + v^2d_{x+1} + v^3d_{x+2} + \cdots)$$

and thereby derive (5) Art. 83.

6. Show that $M_x = vN_x - N_{x+1}$.

7. Compare annual premiums on ordinary life policies of $10,000 for ages 20 and 21 with those for ages 50 and 51. Note the annual change in cost for the two periods of life.

8. Find the net annual premium for a fifteen payment life policy of $10,000 issued at age 50.

9. Find the net annual premium for a ten payment life policy of $25,000 issued at age 55.

10. Find the net annual premium on a twenty payment life policy of $5,000 for your age at nearest birthday.*

11. Compare annual premiums on twenty payment life policies of $10,000 for ages 25 and 26 with those for ages 50 and 51. Note the annual change in cost for the two periods of life.

12. Find the net annual premium for a twenty-five payment life policy of $10,000, issued at age 35.

13. Find the net annual premium for a thirty payment life policy of $10,000, issued at age 35.

14. Using (10) Art. 9 with $n = 1$, and (3) Art. 83, show that $A_x = 1 - da_x$.

15. Show that $P_x = \dfrac{1}{a_x} - d$.

16. Give a verbal interpretation of the formula $A_x = v(1 + a_x) - a_x = va_x - a_x$.

17. Prove that $A_x = v - da_x$.

18. Let $_r | A_x$ denote the net single premium for an insurance of $1 on (x) deferred r years (that is, the benefit is paid only if the insured dies after age $x + r$). Show that

$$_r \big| A_x = \frac{M_{x+r}}{D_x}.$$

84. Term insurance.—*Term insurance is temporary insurance as it provides for the payment of the benefit only in case death occurs within a certain period of n years.* After n years the policy becomes void. The stated period may be any number of years, but usually term policies are for five years, ten years, fifteen years, and twenty years. The symbol $A^1_{x\,\overline{n}|}$ is usually used to denote the net single premium on a term policy of benefit $1 for n years taken at age x.

If we assume that each of l_x persons, all of age x, buys a term policy of benefit $1 for n years, the present value of the payments made by the company will be given by

$$vd_x + v^2 d_{x+1} + v^3 d_{x+2} + \cdots + v^n d_{x+n-1}.$$

Since each of l_x persons buys a benefit of $1, the present value of the premiums paid to the insurance company is $l_x \cdot A^1_{x\,\overline{n}|}$.

Equating the present value of the premiums paid to the company and the present value of the benefits paid by the company, we have

$$l_x \cdot A^1_{x\,\overline{n}|} = vd_x + v^2 d_{x+1} + \cdots + v^n d_{x+n-1}$$

and

$$A^1_{x\,\overline{n}|} = \frac{vd_x + v^2 d_{x+1} + \cdots + v^n d_{x+n-1}}{l_x}. \tag{7}$$

* Your insurance age is that of your nearest birthday.

If both the numerator and the denominator of (7) be multiplied by v^x, we get

$$A^1_{x\,\overline{n}|} = \frac{v^{x+1}d_x + v^{x+2}d_{x+1} + \cdots \text{ to end of table}}{v^x l_x}$$

$$-\frac{v^{x+n+1}d_{x+n} + \cdots \text{ to end of table}}{v^x l_x}.$$

And

$$A^1_{x\,\overline{n}|} = \frac{M_x - M_{x+n}}{D_x}. \tag{8}$$

When the term insurance is for one year only the net premium is called the *natural premium*. It is given by making $n = 1$ in (8). Thus,

$$A^1_{x\,\overline{1}|} = \frac{M_x - M_{x+1}}{D_x} = \frac{C_x}{D_x}. \tag{9}$$

The net annual premium for a term policy of \$1 for n years will be denoted by the symbol $P^1_{x\,\overline{n}|}$. It is evident that the annual premiums for a term policy constitute a temporary annuity due. This annuity is equivalent to the net single premium. Thus,

$$P^1_{x\,\overline{n}|} \cdot a_{x\,\overline{n}|} = A^1_{x\,\overline{n}|}.$$

Solving for $P^1_{x\,\overline{n}|}$ and substituting for $a_{x\,\overline{n}|}$ and $A^1_{x\,\overline{n}|}$, we get

$$P^1_{x\,\overline{n}|} = \frac{M_x - M_{x+n}}{N_x - N_{x+n}}. \tag{10}$$

[(10) Art. 78] and (8) above.

Exercises

1. Find the net single premium for a term insurance of \$5,000 for 15 years for a man aged 30.

Solution. Here, $n = 15$ and $x = 30$. Using (8) Art. 84, we have

$$A^1_{30\,\overline{15}|} = \frac{M_{30} - M_{45}}{D_{30}} = \frac{10,259 - 7,192.81}{30,440.8} = \frac{3,066.19}{30,440.8} = 0.10072$$

and $5,000A^1_{30\,\overline{15}|} = 5,000(0.10072) = \$503.60.$

2. Find the net single premium for a term insurance of \$25,000 for 10 years for a man aged 40.

3. What are the natural premiums for ages 20, 25, 30, 35 and 40 for an insurance of \$1,000.

4. Find the net annual premium for a 20-year term policy of $10,000 taken at age 35.

5. Show that the net annual premium on a k-payment n-year term policy of benefit $1 ($k < n$) taken at age x is given by the expression

$$_kP^1_{x\,\overline{n}|} = \frac{M_x - M_{x+n}}{N_x - N_{x+k}}. \tag{11}$$

6. What is the net annual premium on a 20-payment 40-year term policy of $1,000 for a man aged 20?

7. A person aged 25 buys a $20,000 term policy which will terminate at age 65. Find the net annual premium.

8. Find the net annual premium on a 7-year term policy of $5,000 taken at age 27.

85. Endowment insurance.—*In an endowment policy the company agrees to pay a certain sum in event of the death of the insured within a specified period, known as the endowment period, and also agrees to pay this sum at the end of the endowment period, provided the insured be living to receive the sum.* From the above definition it is evident that an endowment insurance of $1 for n years may be considered as a term insurance of $1 for n years plus an n-year pure endowment of $1. (See Art. 73 and Art. 84.)

Thus, if we let the symbol $A_{x\,\overline{n}|}$ stand for the net single premium for an endowment of $1 for n years, we have

$$A_{x\,\overline{n}|} = A^1_{x\,\overline{n}|} + {}_nE_x$$

$$= \frac{M_x - M_{x+n}}{D_x} + \frac{D_{x+n}}{D_x}$$

$$= \frac{M_x - M_{x+n} + D_{x+n}}{D_x}, \tag{12}$$

since,

$$A^1_{x\,\overline{n}|} = \frac{M_x - M_{x+n}}{D_x} \qquad [(8)\ \text{Art. } 84]$$

and

$${}_nE_x = \frac{D_{x+n}}{D_x}. \qquad [(2)\ \text{Art. } 73]$$

We shall now find the net annual premium for an endowment of $1 for n years, the premiums to be payable for k years. The symbol $_kP_{x\,\overline{n}|}$ will stand for the annual premium of such an endowment. It is clear that

these premiums constitute a temporary annuity due that is equivalent to the net single premium. Hence,

$$_kP_{x\,\overline{n}|} \cdot a_{x\,\overline{k}|} = A_{x\,\overline{n}|}.$$

Solving for $_kP_{x\,\overline{n}|}$ and substituting for $a_{x\,\overline{k}|}$ and $A_{x\,\overline{n}|}$, we get

$$_kP_{x\,\overline{n}|} = \frac{M_x - M_{x+n} + D_{x+n}}{N_x - N_{x+k}}. \tag{13}$$

If the number of annual payments is equal to the number of years in the endowment period, then $k = n$, and (13) becomes

$$P_{x\,\overline{n}|} = \frac{M_x - M_{x+n} + D_{x+n}}{N_x - N_{x+n}}. \tag{14}$$

Exercises

1. Find the net annual premium on a \$5,000 20-payment, 30-year endowment policy taken at age 25.

Solution. Here, $x = 25$, $n = 30$ and $k = 20$. Using (13), we have

$$_{20}P_{25\,\overline{30}|} = \frac{M_{25} - M_{55} + D_{55}}{N_{25} - N_{45}}$$

$$= \frac{11{,}631.1 - 5{,}510.54 + 9{,}733.40}{770{,}113 - 253{,}745}$$

$$= \frac{15{,}853.96}{516{,}368} = 0.0307028,$$

and $\qquad (5{,}000)\,_{20}P_{25\,\overline{30}|} = 5{,}000(0.0307028) = \$153.51.$

2. Find the net annual premium for a \$10,000 twenty payment endowment policy maturing at age 65, taken out at age 21.

3. Find the net annual premium on a \$25,000 15-year endowment policy, taken at age 55.

4. A person aged 22 buys a \$10,000 policy which endows at age 60. Find the net annual premium. The premiums are to be paid until age 60.

5. Find the net single premium on a \$10,000 10-year endowment policy, taken at age 50.

86. Annual premium payable by m equal installments.—In Art. 82 we mentioned the fact that the annual premium may be paid in semi-annual, quarterly or monthly installments.

We shall now find the total annual premium on an ordinary life insurance of \$1, when the premium is payable by m equal installments. The symbol $P_x^{(m)}$ will represent this total premium. It is evident that the premiums constitute an annuity due of $P_x^{(m)}$ per annum, payable in m equal installments of $P_x^{(m)}/m$ each, and the present value of this annuity must equal the net single premium for an insurance of \$1. Hence, we have

$$P_x^{(m)} \cdot \mathrm{a}_x^{(m)} = A_x.$$

Since,

$$\mathrm{a}_x^{(m)} = a_x + \frac{m+1}{2m} \quad \text{[(17) Art. 81]}$$

we have

$$P_{x\_}^{(m)} = \frac{A_x}{a_x + \dfrac{m+1}{2m}}. \tag{15}$$

Example. Find the quarterly premium on an ordinary life policy of \$1,000 taken at age 30.

Solution. Here, $x = 30$ and $m = 4$. From (15), we have

$$P_{30}^{(4)} = \frac{A_{30}}{a_{30} + \frac{5}{8}}$$

$$= \frac{0.33702}{18.6054 + 0.6250} \quad \text{[Table XII]}$$

$$= \frac{0.33702}{19.2304} = 0.01752,$$

and

$$1,000 \cdot P_{30}^{(4)} = 1,000(0.01752) = \$17.52.$$

The quarterly premium is therefore $\frac{1}{4}(\$17.52) = \$4.38$.
Making $m = 1, 2,$ and 4 in (15), we get

$$P_x = \frac{A_x}{1+a_x}, \quad P_x^{(2)} = \frac{A_x}{a_x + \frac{3}{4}}, \quad \text{and } P_x^{(4)} = \frac{A_x}{a_x + \frac{5}{8}}$$

respectively, which shows that twice the semi-annual premium is larger than the annual and four times the quarterly premium is larger than twice the semi-annual. This addition in premium takes account of two things

only: (1) the possibility that a part of the annual premium may be lost in the year of death; and (2) loss of interest on part of annual premium unpaid. On an annual basis the premium would be paid in full at the beginning of the year of death, while on a semi-annual or quarterly basis a part of the premium might remain unpaid at date of death, and the interest on that part of the premium that is not paid at the beginning of the year is lost annually.

However, in practice there is at least another element which is not provided for in this theoretical increase and that is the additional expense incurred in collecting premiums twice or four times a year instead of once. And then, too, it is the observation of most companies that the percentage of lapsed policies is greater when written on the semi-annual and quarterly basis than when written on the annual basis.

It is evident, then, that this theoretical increase is not sufficient to take care of the additional expenses incurred. To obtain the semi-annual premium many companies add 4% to the annual rate and then divide by 2 and to obtain the quarterly premium they add 6% to the annual rate and divide by 4.

We might derive formulas for the annual premiums on other types of policies, but, as indicated above, these formulas are not really used in practice.

Exercises

1. Find the total annual premium on an ordinary life policy $1,000 taken at age 50, if the premiums are to be paid (a) semi-annually; (b) quarterly. Use formula (15) and then use the method that is used in practice by most companies and compare results.

2. Show that (15), Art. 86 can be written.

$$P_x^{(m)} = \frac{M_x}{N_x - D_x\left(\dfrac{m-1}{2m}\right)}.$$

Make $m = 1$ and compare with (5), Art. 83.

3. Find the annual premium on an ordinary life policy of $5,000 taken at age 25, if the premiums are to be paid (a) quarterly; (b) monthly.

87. Summary of formulas of life insurance premiums.—In this chapter we have discussed the "standard" policies and have derived the formulas for computing the net single and the net annual premiums under them. We summarize this information in the following table.

$x =$ the age of the insured; $F =$ the face of the policy.

Name of Policy	Policy Benefits	Premiums Paid	Single Premiums	Annual Premiums
Ordinary life.......	Whole life insurance	For life	$F\dfrac{M_x}{D_x}$	$F\dfrac{M_x}{N_x}$
n-payment life	Whole life insurance	For n years	$F\dfrac{M_x}{D_x}$	$F\dfrac{M_x}{N_x - N_{x+n}}$
n-year term........	n-year term insurance	For n years	$F\dfrac{M_x - M_{x+n}}{D_x}$	$F\dfrac{M_x - M_{x+n}}{N_x - N_{x+n}}$
n-year $\Big\}$ endowment k-payment	(a) n-year pure endowment (b) n-year term insurance	For k years, $k \leqq n$	$F\dfrac{M_x - M_{x+n} + D_{x+n}}{D_x}$	$F\dfrac{M_x - M_{x+n} + D_{x+n}}{N_x - N_{x+k}}$

88. Combined insurance and annuity policies.—The principles summarized in Art. 87 enable us to compute the premiums on the well-known standard policies. Today, combined insurance and annuity policies are frequently written, and we shall now illustrate the methods of computing the premiums for them. We shall merely need to apply the equation of value:

Present value of payments = Present value of benefits. (16)

Example 1. An insurance-annuity contract taken out by a life aged 25 provides for the following benefits:

(a) 10-year term insurance for $5,000,

(b) a pure endowment of $10,000 at the end of 10 years.

It is desired to pay for these benefits in 10 equal annual premiums in advance. What is the annual premium?

Solution. Let P be the required annual premium.

Present value of benefit (a) is $5{,}000 \left(A_{25\,\overline{10|}}^{1}\right) = 5{,}000\,\dfrac{M_{25} - M_{35}}{D_{25}}.$

[(8) Art. 84]

Present value of benefit (b) is $10{,}000 \left({}_{10}E_{25}\right) = 10{,}000\,\dfrac{D_{35}}{D_{25}}.$

[(1′) Art. 80]

Present value of the payments is $P(a_{25\,\overline{10|}}) = P\dfrac{N_{25} - N_{35}}{D_{25}}.$

[(10′) Art. 80]

Hence, using (16), we have

$$P\frac{N_{25} - N_{35}}{D_{25}} = 5,000\frac{M_{25} - M_{35}}{D_{25}} + 10,000\frac{D_{35}}{D_{25}}.$$

$$P = \frac{5000(M_{25} - M_{35}) + 10,000\,D_{35}}{N_{25} - N_{35}}.$$

$$P = \$855.98. \qquad \text{Table XII.}$$

Example 2. An insurance-annuity contract taken out by a life aged 40 provides for the following benefits:

(a) a \$10,000 pure endowment payable at age 65,

(b) a \$10,000 20-payment life insurance,

(c) a life annuity of \$2,000 annually with the first payment at age 65.

If the premiums are to be paid annually in advance for 20 years, find the annual premium P. Set up in commutation symbols.

Solution.

Present value of benefit (a) is $10,000\,(_{25}E_{40}) = 10,000\dfrac{D_{65}}{D_{40}}.$

$$[(1')\ \text{Art. 80}]$$

Present value of benefit (b) is $10,000\,(A_{40}) = 10,000\dfrac{M_{40}}{D_{40}}.$

$$[(2)\ \text{Art. 83}]$$

Present value of benefit (c) is $2,000\,(_{25}\,|\,a_{40}) = 2,000\dfrac{N_{65}}{D_{40}}.$

$$[(8')\ \text{Art. 80}]$$

Present value of the payments is $P(a_{40\,\overline{20|}}) = P\dfrac{N_{40} - N_{60}}{D_{40}}.$

$$[(10')\ \text{Art. 80}]$$

Hence, applying (16), we have

$$P\frac{N_{40} - N_{60}}{D_{40}} = 10,000\frac{D_{65}}{D_{40}} + 10,000\frac{M_{40}}{D_{40}} + 2,000\frac{N_{65}}{D_{40}}.$$

$$P = \frac{10,000\,(D_{65} + M_{40}) + 2,000\,N_{65}}{N_{40} - N_{60}}.$$

Problems

1. Find the net annual premium for an endowment policy for $5,000 to mature at age 85 and taken at age 40.

2. For purposes of valuation, a policy for $15,000 taken at age 35 provides that the insurance of the first year is term insurance, and that of subsequent years is a 14 payment life insurance on a life aged 36, so that the insurance is paid up in 15 payments in all. What is the first year premium and that of any subsequent year?

3. An insurance contract provides for the payment of $1,000 at the death of the insured, and $1,000 at the end of each year thereafter until 10 installments certain are paid. What is the net annual premium on such a contract for a person aged 40, if the policy is to become paid up in 20 payments?

4. What would be the net annual premium in Problem 3, if it were written on the ordinary life basis?

5. Assume that each of l_x persons, all of age x, buys an n-payment life policy of $1; equate the present value of all premiums paid and all benefits received; and derive (6), Art. 83.

6. Reasoning as in Problem 5, derive (10), Art. 84.

7. Reasoning as in Problem 5, derive (14), Art. 85.

8. Prove that:

$$\text{(a) } A_x = \frac{P_x}{P_x + d}, \qquad \text{(b) } P_x = \frac{dA_x}{1 - A_x}.$$

9. Prove that:

$$\text{(a) } A^1_{x\,\overline{1}|} = v \cdot \frac{d_x}{l_x}, \qquad \text{(b) } A^1_{x\,\overline{n}|} = v a_{x\,\overline{n}|} - a_{x\,\overline{n}|}.$$

10. Show that

$$A_{x\,\overline{n}|} = v a_{x\,\overline{n}|} - a_{x\,\overline{n-1}|},$$

and interpret this formula verbally.

11. A 20-payment life insurance policy for $1,000 issued to a life aged 30, for purposes of valuation, is treated as a one-year term policy at age 30 plus a 19-payment life policy at age 31. What is the net premium for the first year and the net level annual premium for the subsequent 19 payments?

12. For purposes of valuation, an ordinary life policy of $1,000 issued to a life aged 30 is considered as a one-year term policy at age 30 and an ordinary life policy at age 31. What is the first net annual premium and the subsequent annual net level premiums?

13. A person aged 45 takes out a policy which promises $10,000 if death occurs before age 65. If the insured is living at age 65, he is to receive $1,000 annually as long as he lives, the first $1,000 being paid when age 65 is reached. What is the net level annual premium if the policy is issued on a 20-payment basis?

14. A life insurance policy issued on a life aged 30 provides for the following benefits: In the event of death of the insured during the first 30 years the policy pays $1,000, with a $5,000 cash payment if the insured survives to age 60. If the policy is issued on a 20-payment net level basis, find the net premium.

Find the net periodic premium for each of the following policies.

Problem	Benefits of Policy	Age of Insured	Number of Annual Premiums
15.	(a) 10-year term insurance for $10,000, (b) a pure endowment of $20,000 at end of 20 years.	45	10
16.	(a) Whole life insurance of $10,000, (b) a pure endowment at age 60 of $10,000, (c) a life annuity of $1,000 annually with first payment at age 65.	30	20
17.	(a) $30,000 to beneficiary if death of insured occurs between ages 30 and 40, (b) $25,000 to beneficiary if death of insured occurs between ages 40 and 50, (c) $15,000 to beneficiary if death of insured occurs between ages 50 and 60.	30	20

Hint. The benefits under the policy in Problem 17 are the same as those under a policy providing for $5,000 10-year term insurance, $10,000 20-year term insurance, $15,000 30-year term insurance, all issued to a life aged 30.

CHAPTER X

VALUATION OF POLICIES. RESERVES

89. Meaning of reserves.—Except at very low ages, the probability of dying in any year increases with increasing age. Consequently, the cost of insurance provided by the given policy, as indicated by the natural premium, increases with increasing age. The net level annual premium for the policy is larger than the natural premium during the early years of the policy and is therefore more than sufficient to cover the insurance, but, in the later years of the policy the net level premium is smaller than the natural premium and is therefore insufficient to cover the cost of the insurance.

To illustrate the above remarks, let us consider a numerical example. A man aged 35 takes out a $1,000 ordinary life policy. The net level annual premium under the American Experience 3½% Table is $19.91. The cost of insurance (natural premium) for the first policy year is $8.64, leaving a difference ($19.91 − $8.64) = $11.27. During the second year of the policy the cost of insurance (natural premium on a life aged 36) is $8.78, and thus the insured pays ($19.91 − $8.78) = $11.13 more than the expense due to mortality. This situation continues to age 57 when, and for later years, the net level premium $19.91 is insufficient to meet the cost of insurance, for, at age 57 the natural premium is $20.61. The following table compares the net level premium $19.91 with the increasing cost of insurance for an ordinary life policy of $1,000 on a life aged 35.

Attained Age	Natural Premium	Excess N.L.P.–N.P.	Attained Age	Natural Premium	Excess N.L.P.–N.P.
35	$8.64	$11.27	65	$38.77	−$18.86
40	9.46	10.45	70	59.90	− 39.99
45	10.79	9.12	75	91.18	− 71.27
50	13.32	6.59	80	139.58	−119.67
55	17.94	1.97	85	227.59	−207.68
60	25.79	−5.88	90	439.17	−419.26

It is evident that if an insurance company is to operate upon a solvent basis, it must accumulate a fund during the early policy years to meet the increased cost in the later policy years. These excesses of the net level premium over the natural premiums that appear in the early policy years are improved at interest and held by the company to meet the increased cost during the later policy years. The accumulation of these excesses results in a fund that is called the *reserve* or *the value of the policy*.*

90. Computing reserves, Numerical illustration.—A glance at the American Experience Table of Mortality shows that of 100,000 persons alive at age 10 there remain 81,822 alive at age 35.

Let us assume that each of 81,822 persons, all aged 35, buys an ordinary life policy of $1,000. The total of the net annual premiums amounts to $1,629,076.02. This amount accumulates to $1,686,093.68 by the end of the first year. According to the table of mortality the death losses to be paid at the end of the first year amount to $732,000.00, leaving $954,093.68 in the reserve. This leaves a terminal reserve of **$11.77** to each of the 81,090 survivors. The premiums received at the beginning of the second year amount to $1,614,501.90, which when added to $954,093.68 makes a total of $2,568,595.58, and so on. The following table is self explanatory.

TABLE SHOWING TERMINAL RESERVES ON AN ORDINARY LIFE POLICY FOR $1,000
ON THE LIFE OF AN INDIVIDUAL AGED 35 YEARS

Policy Year	Funds on Hand at Beginning of Year	Funds Accumulated at 3½%	Death Losses	Funds at End of Year	Amount to Credit of Each Survivor, Reserve
1	$1,629,076.02	$1,686,093.68	$732,000	$ 954,093.68	$11.77
2	2,568,595.58	2,658,496.43	737,000	1,921,496.43	23.91
3	3,521,324.66	3,644,571.02	742,000	2,902,571.02	36.46
4	4,487,625.03	4,644,692.94	749,000	3,895,692.94	49.40
5	5,465,835.36	5,657,139.60	756,000	4,901,139.60	62.75
..	....	....	.....	....	......

This illustrates what is known as the *retrospective method* of computing reserves because the reserve at the end of any policy year was determined exclusively from facts that belong to the *past history* of the policy.

* The reserve on any one policy at the end of any policy year is known as the terminal reserve for that year, or the policy value.

<div align="center">Exercises</div>

1. The premium on a 5-year endowment insurance for $1000 taken out at age 25 is $183.56. Complete the following table and show that at the end of 5 years the fund is just sufficient to pay each survivor $1000.00.

Policy Year	Funds on Hand at Beginning of Year	Funds Accumulated at $3\frac{1}{2}\%$	Death Losses	Funds at End of Year	Amount to Credit of Each Survivor, Reserve
1	$16,342,713.92	$16,914,708.91	$718,000	$16,196,708.91	$183.40
2	32,407,626.75	33,541,893.69	718,000	32,823,893.69	374.72
3	48,903,015.45	50,614,620.99	718,000	49,896,620.99	574.33
4			718,000		
5			719,000		

2. The annual premium on a 10-payment life policy on a life aged 30 is $40.6078. Prepare a table similar to that in Exercise 1 and thus compute the reserve on the policy at the end of each policy year.

91. Fackler's accumulation formula.—We will now develop a formula which expresses the terminal reserve of any policy year in terms of the reserve of the previous year. We will designate by $_rV_x$ the terminal reserve of the rth year on an insurance of $1, and let P_x stand for the net annual premium. The reserve then at the beginning of the $(r + 1)$th year will be $_rV_x + P_x$. This is called the initial reserve of the $(r + 1)$th year. The aggregate reserve at the beginning of the $(r + 1)$th year, for the l_{x+r} individuals insured, will be

$$l_{x+r}(_rV_x + P_x).$$

This last amount will accumulate, by the end of the year, to

$$l_{x+r}(_rV_x + P_x)(1 + i).$$

Out of this amount the company will have to pay d_{x+r} as death claims for the year, leaving

$$l_{x+r}(_rV_x + P_x)(1 + i) - d_{x+r}$$

as the total reserve to the l_{x+r+1} surviving policy holders at the end of the $(r + 1)$th year.

The terminal reserve then for the $(r + 1)$th year is

$$_{(r+1)}V_x = \frac{l_{x+r}(_rV_x + P_x)(1 + i) - d_{x+r}}{l_{x+r+1}}$$

$$= \frac{(1 + i)l_{x+r}}{l_{x+r+1}}(_rV_x + P_x) - \frac{d_{x+r}}{l_{x+r+1}}. \qquad (1)$$

If we now define the valuation factors (see Table XIII)

$$u_x = \frac{(1 + i)l_x}{l_{x+1}} \quad \text{and} \quad k_x = \frac{d_x}{l_{x+1}},$$

we have

$$_{(r+1)}V_x = u_{x+r}(_rV_x + P_x) - k_{x+r}. \qquad (2)$$

This formula is known as *Fackler's accumulation formula*.   It will evidently work for any policy, for the factors u_{x+r} and k_{x+r} in no way depend upon the form of the policy.   This formula is used very extensively by actuaries in preparing complete tables of terminal reserves.   The valuation functions u_x and k_x are based upon the American Experience Table of Mortality and $3\frac{1}{2}\%$ interest and are given in Table XIII.

To find the terminal reserve for the first policy year we make $r = 0$, and (2) becomes

$$_1V_x = u_xP_x - k_x, \qquad (3)$$

for it is evident that $_0V_x = 0$.

Exercises

1. Show that $u_x = \dfrac{D_x}{D_{x+1}}$ and $k_x = \dfrac{C_x}{D_{x+1}}$ and verify the tabular values of u_x and k_x for the ages 20, 25, and 30 by making use of the C_x and D_x functions.

2. Making use of formulas (3) and (2) Art. 91, verify the reserves in the problem of Art. 90.

Solution.   From (3) we have

$$_1V_{35} = u_{35}P_{35} - k_{35}, \text{ and } P_{35} = 0.01991.$$

Hence

$$_1V_{35} = 1.044343\,(.01991) - 0.009027$$

$$= 0.011766.$$

Then, $1{,}000\ _1V_{35} = \$11.77.$

Also, $_2V_{35} = u_{36}\,(_1V_{35} + P_{35}) - k_{36}, \quad [(2) \text{ Art. 91}]$

$$= 1.044493\,(0.011766 + 0.01991) - 0.009172$$

$$= 0.023913.$$

Hence, $\qquad 1{,}000 \, {}_2V_{35} = \$23.91.$

$$ {}_3V_{35} = ? $$

3. Find the terminal reserve for each of the first five policy years on a ten payment life policy for $5,000 taken at age 25.

4. The terminal reserve at the end of the fifteenth policy year on a twenty-year endowment policy for $1,000 taken at age 25 is $665.59. Calculate the terminal reserves for the succeeding policy years until the policy matures.

5. The terminal reserve at the end of the tenth policy year on a fifteen payment life policy for $1,000 taken at age 30 is $272.96. Find the terminal reserve for the eleventh and twelfth years.

6. The terminal reserve at the end of the twenty-fifth policy year on an ordinary life policy for $1,000 taken at age 29 is $333.81. Find the terminal reserve for the twenty-sixth year.

92. Prospective method of valuation.—We now consider another method of valuation and derive a formula for determining the terminal reserve for any policy year independent of the reserve for the previous year. *At the end of the rth policy year the sum of the terminal reserve and the present value of the future premiums to be paid must equal the net single premium for a new policy on the life of the insured, who is now aged $x + r$.*

If we consider an ordinary life policy the present value of the future premiums to be paid would be $P_x a_{x+r}$ and the net single premium for a policy on the insured, now aged $x + r$, would be A_{x+r}. Again denoting the terminal reserve for the rth year by ${}_rV_x$, we obtain the relation,

$$ {}_rV_x + P_x a_{x+r} = A_{x+r}, \qquad [(5) \text{ Art. 76}] $$

and

$$ {}_rV_x = A_{x+r} - P_x a_{x+r}. \qquad (4) $$

We see from equation (4) that *the rth year terminal reserve is equal to the net single premium for the attained age $x + r$ minus the present value of all future net annual premiums.* This definition of reserve will evidently hold for all forms of policies.

The value of ${}_rV_x$ may be expressed in terms of the commutation columns by remembering that

$$ A_{x+r} = \frac{M_{x+r}}{D_{x+r}}, \qquad [(2) \text{ Art. 83}] $$

$$ P_x = \frac{M_x}{N_x}, \qquad [(5) \text{ Art. 83}] $$

and

$$a_{x+r} = \frac{N_{x+r}}{D_{x+r}} \qquad [(6) \text{ Art. 76}]$$

Then

$$_rV_x = \frac{N_x M_{x+r} - M_x N_{x+r}}{N_x D_{x+r}} \qquad (4')$$

Replacing A_{x+r} by its equivalent $P_{x+r}(a_{x+r})$, equation (4) becomes

$$_rV_x = (a_{x+r})P_{x+r} - (a_{x+r})P_x,$$

or

$$_rV_x = (P_{x+r} - P_x)(a_{x+r}). \qquad (5)$$

P_{x+r} is the net annual premium for an individual now aged $x + r$, but since he took his insurance at age x instead of waiting until age $x + r$, his annual saving in premium is $(P_{x+r} - P_x)$ and the present value of these annual savings is $(P_{x+r} - P_x)(a_{x+r})$ which is the policy reserve at the end of the rth year. Hence we have a verbal interpretation of the formula (5).

We will now derive an expression for the terminal reserve for the rth year on an n-payment life insurance of \$1. The symbol, $_{r:n}V_x$, will denote the rth year reserve for this policy. Immediately following equation (4), Art. 92, we defined reserve and said this definition would hold for all forms of policies. Here the net single premium for the attained age $x + r$ would be A_{x+r} and the present value of all future premiums would be given by

$$_nP_x \cdot a_{x+r\,\overline{n-r|}}$$

as they would constitute a temporary life annuity due, for $n - r$ years. Consequently, we may write

$$_{r:n}V_x = A_{x+r} - {}_nP_x \cdot a_{x+r\,\overline{n-r|}} \qquad (6)$$

Denoting the rth year terminal reserve on a k-payment n-year endowment insurance of \$1 by $_{r:k}V_{x\,\overline{n|}}$ and following the same line of reasoning used in obtaining (6), we get,

$$_{r:k}V_{x\,\overline{n|}} = A_{x+r\,\overline{n-r|}} - {}_kP_{x\,\overline{n|}} \cdot a_{x+r\,\overline{k-r|}}. \qquad (7)$$

When r is equal to or greater than k formula (7) becomes

$$_{r:k}V_{x\,\overline{n|}} = A_{x+r\,\overline{n-r|}}. \qquad (8)$$

When the annual premiums are payable for the entire endowment period, $k = n$, and (7) reduces to

$$_rV_{x\,\overline{n}|} = A_{x+r\,\overline{n-r}|} - P_{x\,\overline{n}|} \cdot a_{x+r\,\overline{n-r}|}. \tag{9}$$

Exercises

1. Find the 20th year reserve on an ordinary life policy for $5,000 taken at age 30.

Solution. Here, $r = 20$, $x = 30$. Then from (4) Art. 92, we have

$$_{20}V_{30} = A_{50} - P_{30}\,(a_{50}).$$

But

$$P_{30} = \frac{M_{30}}{N_{30}} = \frac{10{,}259}{596{,}804} = 0.01719.$$

Hence,

$$_{20}V_{30} = 0.50849 - 0.01719(14.5346)$$

$$= 0.25864,$$

and

$$5{,}000 \cdot {}_{20}V_{30} = \$1{,}293.20.$$

2. Find the terminal reserve of the 15th policy year on a 15-payment life policy of $5,000 taken at age 35. Explain why this result equals the net single premium on a life policy taken at age 50.

3. Find the 20th year terminal reserve on a $10,000 policy which is to mature as an endowment at age 65, if the policy was taken at age 30.

4. Find the 10th year reserve on a $20,000, 20-year endowment policy taken at age 40.

5. Find the terminal reserve of the seventh policy year on a twenty payment life policy of $2,500 taken at age 32.

6. Find the terminal reserve of the ninth policy year on an ordinary life policy of $5,000 taken at age 40.

7. Verify the result for the third terminal reserve in Exercise 1, Art. 90.

8. Verify the result for the fifth terminal reserve of the illustrative problem in Art. 90.

9. Reduce formula (6) Art. 92 to commutation symbols.

93. Retrospective method of valuation.—In preceding sections we have alluded to the retrospective method of computing reserves. Fackler's accumulation formula, Art. 91, was developed from facts that pertain to the *past history* of the policy. It expresses the reserve of any policy year in terms of the reserve of the previous year, and is therefore very useful in preparing *complete* tables of terminal reserves. It cannot be used, however, for computing the reserve on a given policy for a *specified* policy year.

The problem of finding the reserve on a given policy for a specified policy

year was solved in Art. 92 by the prospective method.   The thoughtful student will naturally enquire: "Can we develop formulas by the retrospective method for computing the reserves on given policies for specified policy years, and are the results consistent with those of Art. 92?"

We answer both questions in the affirmative.

From the retrospective point of view, the *rth terminal reserve for a given policy issued at age x is the accumulated value at age x + r of the past premiums less the accumulated value at age x + r of the past insurance benefits.*   The past insurance benefits are those of an *r*-year term insurance on (*x*).   That is,

$$\begin{pmatrix} r\text{th Terminal} \\ \text{reserve} \end{pmatrix} = \begin{pmatrix} \text{Value at age} \\ x + r \\ \text{of past premiums} \end{pmatrix} - \begin{pmatrix} \text{Value at age} \\ x + r \\ \text{of past benefits} \end{pmatrix}$$

Consider an ordinary life policy of $1 on (*x*).

P_x = the net annual premium, and $_rV_x$ = the *r*th terminal reserve.

$$\begin{pmatrix} \text{Value at age } x + r \\ \text{of past premiums} \end{pmatrix} = P_x \cdot {}_r u_x = \frac{M_x}{N_x} \cdot \frac{N_x - N_{x+r}}{D_{x+r}}.$$

[(5) Art. 83]   [(12) Art. 79]

$$\begin{pmatrix} \text{Value at age } x + r \\ \text{of past benefits} \end{pmatrix} = \frac{A^1_{x\overline{r}|}}{_rE_x} = \frac{M_x - M_{x+r}}{D_x} \cdot \frac{D_x}{D_{x+r}} = \frac{M_x - M_{x+r}}{D_{x+r}}.$$

[(8) Art. 84]   [(2) Art. 73]

Hence,

$$_rV_x = \frac{M_x}{N_x} \cdot \frac{N_x - N_{x+r}}{D_{x+r}} - \frac{M_x - M_{x+r}}{D_{x+r}}.$$

$$_rV_x = \frac{N_x M_{x+r} - M_x N_{x+r}}{N_x D_{x+r}}$$

which is the same as (4') Art. 92.

Problems

1. How much does a person save by buying a $10,000 ordinary life policy at age 25 instead of waiting until age 30? See formula (5), Art. 92.

2. Show that when $r = n$, the right-hand member of (6) Art. 92, reduces to A_{x+n} and explain the meaning of this result.

3. Derive formula (7), Art. 92.

4. To what does the right member of (9) reduce when $r = n$?

5. Express formula (6) in terms of the commutation symbols.

6. Express formula (9) in terms of the commutation symbols.

7. Making use of (3) and (5) Art. 83, show that

$$_rV_x = \frac{a_x - a_{x+r}}{1 + a_x} = 1 - \frac{1 + a_{x+r}}{1 + a_x} = 1 - \frac{a_{x+r}}{a_x}. \tag{10}$$

8. Use formula (10) to find the twelfth year terminal reserve on a $2,000 ordinary life policy taken at age 37.

9. (a) Show that $_{r:n}V_x = (_{n-r}P_{x+r} - {}_nP_x)\,(a_{x+r}\,\overline{{}_{n-r|}})$ and interpret the result.

(b) Derive a similar expression for the n-year endowment policy.

10. Build up a table of terminal reserves for the first 10 years on a 20-payment life policy of $1,000 taken at age 30. Use (3) and (2), Art. 91 and check every 5 years by using (6), Art. 92.

11. Build up a table of terminal reserves for the first 10 years on an ordinary life policy of $1,000 taken at age 33. Use (3) and (2) Art. 91 and check for the fifth and tenth years by using formula (10), Problem **7.**

12. Build up a table of terminal reserves for the first 5 years on a 10 year endowment of $1,000 taken at age 30. Use Fackler's formula and check the fifth year by using formula (9) Art. 92.

13. Solve Exercise 10, with the policy taken at age 40.

14. Solve Exercise 11, with the policy taken at age 38.

15. Develop a formula similar to (9), Art. 92, but for term insurance for a term of n years. Find the fifth year terminal reserve on a ten year term policy of $1,000 issued at age 30.

16. Find the seventh year terminal reserve on a $1,000, 15 year term policy issued at age 40.

CHAPTER XI

GROSS PREMIUMS, OTHER METHODS OF VALUATION, POLICY OPTIONS AND PROVISIONS, SURPLUS AND DIVIDENDS

94. Gross Premiums.—In Chapter IX a net premium was defined and we found the net premiums for a number of the standard policies. We saw that this net premium was large enough to take care of the yearly death claims and to build up a reserve sufficient to care for all future claims, but was not adequate to pay the running expenses of the company and provide against unforeseen contingencies.* Hence to care for these extra expenses a charge in addition to the net premium must be made. *This additional charge is sometimes spoken of as a loading, and the net premium plus this loading is called the gross premium.*

In Chapter IX we enumerated some of the expenses of the insurance company. To these we may add taxes imposed by state legislatures, medical expenses for the examination of new risks, expenses for collecting premiums, and many other minor ones.

We shall now discuss some of the methods used in arriving at a sufficient gross premium. At first thought it might seem reasonable to add a fixed amount to the net premium on each $1,000 insured regardless of age or kind of policy. This would give the same amount for expenses on an ordinary life policy for a young man, aged 25 say, as on a 20-year endowment policy for the same amount and age. The percentage of loading on the ordinary life policy would be about three times as large as that on the endowment policy, while as a matter of fact the expenses of each policy would be about the same percentage of the respective premium, for commissions are usually paid as a percentage of the premium, and taxes are charged in a like manner. Hence, we see that a constant amount added to a premium does not make adequate provisions and it is seldom used now without modification.

Sometimes loadings are effected by adding a fixed percentage of the net premium. Let us assume for the time being that this is 30%. Then the loading at age 25 on an ordinary life policy would be $4.53 and on a ten year endowment at age 65 it would be $32.75. It is evident that this method makes the loading very high for the older ages and thereby causes the premium to be unattractive to the applicant. As a matter of fact the

---

* The influenza epidemic of 1918 is an example of this.

$32.75 is more than is actually required to care for the expenses of the 10-year endowment taken at age 65. This method has its objections as well as the first method described.

Often a constant amount plus a fixed percentage of the net premium is added. This is a combination of the two methods described above. The constant gives an adequate amount for administration expenses as this depends more on the volume of insurance in force than on the amount of premiums, and the percentage provides for those expenses that are a certain percentage of the net premium.

If we add a constant $4 for each $1,000 of insurance and 15% of the net premium we get a premium that is very satisfactory. For example the net premium on an ordinary life policy of $1,000 at age 35 is $19.91. Adding $4.00 and 15%, we get $26.89 as our office premium.

Another plan is a modification of the percentage method. If $33\frac{1}{3}\%$ be the percentage, $\frac{1}{3}$ of the net premium is added to obtain the office premium on ordinary life. On limited payment life and endowment policies $\frac{1}{6}$ of the net premium for the particular policy is added and then $\frac{1}{6}$ of the net premium on an ordinary life for the same age. To illustrate:

Ordinary life, net rate, age 35..................	$19.91
$\frac{1}{3}$ of net rate	6.64
Gross premium........................	$26.55
20-year endowment, net rate, age 35.............	$40.11
$\frac{1}{6}$ of $40.11................................	6.68
$\frac{1}{6}$ of ordinary life rate......................	3.32
Gross premium........................	$50.01

If we let P_x' stand for the gross premium of an ordinary life policy of $1, and let r denote the rate of the percentage charge, and c the constant charge per $1,000 of insurance, we may express by the formula,

$$P_x' = P_x(1 + r) + \frac{c}{1,000},\qquad (1)$$

the ideas mentioned above. If the loading is a constant charge, r will be zero but if it is considered a percentage charge only, c will be zero. Formula (1) may be modified to apply to the different forms of policies. Nearly every company has its individual method of calculating gross premiums but all companies get about the same results.

95. Surplus and dividends.—The gross premium is divided into three parts. The *first part* is an amount sufficient to pay the death claims for

the year, where the number of deaths is based upon the American Experience Table of Mortality. The *second part* goes to build up the reserve. The *third part* is set aside to meet the expenses of the company.

As all new policy holders are selected by medical examination it is reasonable to expect that, under normal conditions, the actual number of deaths will be much smaller than the expected. Hence, a portion of the first part of the premium is not used for the current death claims, and is placed in a separate fund known as the *surplus*.

The reserve is figured on a $3\frac{1}{2}\%$ interest basis, but the average interest earned by the funds of the company is usually considerably more than this. This additional interest is also added to the *surplus*.

After an insurance company has become well organized and its territory has been thoroughly developed its annual expenses are usually much less than the expected. Hence a portion of the third part of the premium is saved and added to the *surplus*.

Since the surplus comes from savings on the premiums, a part of it is refunded to the policy holders at the end of each year. These refunds are called *dividends*, but they are not dividends in the same sense as the interest on a bond. Most of these dividends come from savings on premiums and only a small amount comes from a larger interest earning on the reserve and other invested funds.

A large portion of this surplus must be held by the company for it is as essential for an insurance company to have an adequate surplus as it is for a trust company, a bank, or any other corporation. The surplus represents the difference between the assets and the liabilities, and a relatively large surplus is an indication of solvency.

96. Policy options.—In any standard life-insurance policy there is a nonforfeiture table giving the surrender or loan value, automatic extended insurance, and paid-up insurance at the end of each policy year beginning with the third.* In case the insured desires to quit paying any time after three annual payments have been made, he may surrender his policy and receive the cash value indicated in the table, or a paid-up policy for the amount indicated in the table. Or he may keep his policy and remain insured for the full face amount of the policy for the time stated in the table.

97. Surrender or loan value.—The surrender or loan value of a policy at the end of any policy year is the terminal reserve for that year less whatever charge (known as a surrender charge) the company makes for a surrender. This charge is a per cent of the terminal reserve and decreases

* Some companies begin the non-forfeiture table at the end of the second year.

each year. After 10 or 15 years there is usually no charge made upon surrender. The surrender value at the end of the tenth year on an ordinary life $1,000 policy, issued to a person age 25, is $89.43 less the surrender charge. Insurance laws allow companies to make a surrender charge. The companies, however, usually make a smaller charge than is allowed them by law.

We give a few reasons for this charge: *First*, the company is at an expense to secure a new policy holder in place of the one surrendered; *Second*, life insurance companies claim that the greatest number of lapses come from people who are in excellent health rather than from those in poor health. This would tend to increase the percentage of mortality and thereby decrease the surplus and dividends to policy holders. *Third*, if policy values were not subjected to a surrender charge, it is the belief that a large number of policy holders would either surrender their insurance or take the full loan value during hard times and thus cause financial loss to the company.*

98. Extended insurance.—Whenever the insured fails to pay his annual premium the company automatically extends his insurance for the full face of the policy unless he surrenders his policy and requests the surrender value or paid-up insurance. The length of time that the company can carry the insurance for the full amount, without further premiums, depends upon the surrender value of the policy at that time.

In order to find the time of extension we must solve the equation

$$\frac{M_{x+r} - M_{(x+r)+t}}{D_{x+r}} = {}_rV_x \quad \text{[(8) Art. 84]} \tag{2}$$

for t. An example will show how this is done.

Example. The value at the end of the tenth year, of an ordinary life policy of $1,000, taken at age 25, is $89.43. Find the time of the automatic insurance.

Solution. Here, $x = 25$, $r = 10$, ${}_{10}V_{25} = 0.08943$, and

$$\frac{M_{35} - M_{35+t}}{D_{35}} = 0.08943$$

or

$$
\begin{aligned}
M_{35+t} &= M_{35} - (0.08943)D_{35} \\
&= 9,094.96 - (0.08943)(24,544.7) \\
&= 6,899.93.
\end{aligned}
$$

* For a more complete discussion of surrender values see " Notes on Life Insurance " by Fackler.

This value of M_{35+t} lies between M_{46} and M_{47}. By interpolation we find that $35 + t = 46$ years 9 months, approximately, or $t = 11$ years 9 months. Hence, the value \$89.43 is enough to buy a term policy of \$1,000 for 11 years and 9 months.

99. Paid-up insurance.—If at any time the insured surrenders his policy he may take a paid-up policy for the amount that his surrender value at that time will purchase for him at his attained age. For example, the value at the end of the tenth year, of an ordinary life policy of \$1,000 taken at age 25 is \$89.43. Find the paid-up insurance for that year. The insured is now age 35 and an insurance of \$1 will cost him

$$A_{35} = 0.37055.$$

Hence, he may buy for \$89.43 as much insurance as .37055 is contained in \$89.43, or approximately \$241.00.

The following is a non-forfeiture table for the first 10 years on an ordinary life policy for \$1,000 taken at age 25:

NON-FORFEITURE TABLE—\$1,000, ORDINARY LIFE, AGE 25

At End of	Cash or Surrender Value	Automatic Extension		Paid-up Insurance
		Years	Months	
3rd Year	\$23.70	3	1	\$73.00
4th "	32.16	4	2	97.00
5th "	40.91	5	5	121.00
6th "	49.98	6	7	146.00
7th "	59.35	7	10	170.00
8th "	69.04	9	2	194.00
9th "	79.07	10	5	218.00
10th "	89.43	11	9	241.00

In the above table the values are all based upon the full level net premium terminal reserves. In a standard policy these values would all be some smaller due to the surrender charge. Usually, only even dollars are published in non-forfeiture tables. If the preliminary term method or modified preliminary term methods of valuation are used,* all the values will be made somewhat smaller for the first few policy years.

* These methods are discussed in later sections.

We shall now outline a method for determining the surrender values, automatic extended insurance, and paid-up insurance for an endowment policy. The surrender values will be determined just as terminal reserves are determined (the surrender value is the terminal reserve less the surrender charge). The time for automatic extension must at no time extend beyond the date of maturity. Hence, only such a part of the surrender value will be used as is necessary to extend the insurance to the maturity date. The balance of the surrender value for that year will go to buy a pure endowment which will mature at the end of the endowment period. Let us consider a $1,000, 20-year endowment for an individual aged 30.

The reserve (full level net premium method) for the fifth year is $177.83. The cost of a 15-year paid-up term policy of $1,000 for the attained age, 35, is $111.61. This leaves $(177.83 - 111.61) = \$66.22$ with which to purchase a 15-year pure endowment. A pure endowment of $1 will cost

$$_{15}E_{35} = 0.50922. \quad [(2) \text{ Art. 73}]$$

Hence, $66.22 will buy as much pure endowment as 0.50922 is contained in 66.22, or $130.00 (nearest dollar).

We now find the amount of the 15-year paid-up endowment that $177.83 will buy. The cost of a $1, 15-year paid-up endowment for age 35 is $0.62083. Hence, $177.83 will buy a paid-up endowment of

$$\frac{177.83}{0.62083} = \$286.00 \text{ (approximately)}.$$

The following is a non-forfeiture table for the first 10 years on a 20-year endowment of $1,000 taken at age 30:

NON-FORFEITURE TABLE—$1,000, 20-YEAR ENDOWMENT, AGE 30

At end of	Cash or Surrender Value	Automatic Extension		Pure Endowment	Paid-up Endowment
		Years	Months		
3rd Year	$102.35	14	4	......	$175.00
4th "	139.32	16	no	$47.00	231.00
5th "	177.83	15	"	130.00	286.00
6th "	217.95	14	"	208.00	341.00
7th "	259.74	13	"	282.00	394.00
8th "	303.29	12	"	353.00	447.00
9th "	348.67	11	"	421.00	498.00
10th "	395.98	10	"	491.00	554.00

In the above table the values are all based upon the full level net premium terminal reserves. However, these values would all be somewhat smaller due to the surrender charge.

In the event the policy holder paid only five premiums and then lapsed his policy, he could accept any one of the following options at the end of five years: Receive $177.83 (less surrender charge) in cash, receive a paid-up 15-year term policy for $1,000 and $130 in cash at age 50, if living, or receive a paid-up endowment for $286.00.

Exercises

1. Make a non-forfeiture table for the first 10 years of a $1,000 ordinary life policy taken at age 40.

2. Make a non-forfeiture table for the first 10 years of a $1,000 20-payment life policy taken at age 40.

3. Make a non-forfeiture table for the first five years of a $1,000 20-year endowment policy taken at age 40.

4. Make a non-forfeiture table for the first 10 years of a $1,000 policy taken at age 26, which is to endow at age 60.

5. A man who has attained the age of 35 surrenders his policy and chooses to elect the option which grants him extended insurance to the amount of $5,000 for eight years. Find his surrender value.

6. A man who has attained the age of 35 surrenders his policy and elects the option of paid-up insurance. If his surrender value is $5,000, find the amount of insurance he should receive.

7. A man aged 25 took out a convertible $10,000 10-year term policy. At the end of 5 years he converted it into an ordinary life policy as of his attained age. How much ordinary life insurance did he obtain if all his reserve was used for that purpose?

8. A man aged 30 takes out an ordinary life policy for $10,000. When he is 55 years of age, the company decides to go out of business. What sum is due him?

100. Preliminary term valuation.—In Chapter X we considered what is known as the *full level premium* method of valuation. *By this method the difference between the net annual premium and the natural premium for the first year is placed into the reserve.* It is clear that this leaves none of the net annual premium to care for the *first year's expenses* of the policy. The initial expenses of a policy are the greatest for they include an agent's commission, medical examiner's fee, taxes, etc. To illustrate the above remarks let us consider an ordinary life policy of $1,000 taken at age 35. The net annual premium on this policy is $19.91 and the office premium is $26.55, leaving only $6.64 to go towards initial expenses. The balance of the first year's expenses must come from the surplus. But this seems

unfair to the old policy holders as their contributions in the way of premiums have built up this surplus.   It is perhaps fair that they should bear a small portion of the expenses of securing new business, but they should not pay so much as is required under the full level premium method of valuation.   It is also evident that under this method it would be almost impossible for a new company to build up an adequate surplus.

A method known as a *preliminary term system* has been devised to meet the objections mentioned above, and we will now describe it.   *Under this method all the first year premium is available for current mortality and expenses.   The first year's insurance then is term insurance and the policy provides that it may be renewed at the end of the first year as a life or endowment policy at the same office premium.   The net premium for the first year is the natural premium for the age when the policy was issued and the balance of the gross premium is considered as first year loading and is available for initial expenses.   The net premium for the second and subsequent years is the net premium at an age one year older than when the policy was issued.*

Let us again consider the ordinary life policy of $1,000 taken at age 35. Here the office premium is $26.55 and since the natural premium for the first year is $8.65 there would be a first year loading of $17.90.   The net annual premium for subsequent years would be $20.55 * which would leave $6.00 as a renewal loading.   Had the policy been issued under the full level net premium system there would have been a uniform loading of $6.64.

A 20-payment life policy taken at age 35 would have a gross premium of $35.70.   The first year natural premium would be $8.65, thus leaving a loading of $27.05 for initial expenses, and the net premium for the subsequent nineteen years would be the net premium on a 19-payment life policy as of age 36.   This would be $28.89, thus resulting in a renewal loading of $6.81.   Had this policy been issued under the full level net premium system there would have been a uniform loading of $8.31.

The preliminary term method when applied to ordinary life policies and limited payment life and endowment policies with long premium paying periods is sound in principle and is recognized by the best authorities. However, the system has some objections when it is applied to limited payment life and endowment policies of short premium paying periods. These objections will be discussed in Art. 101 and a remedy will be devised.

It is evident that, since the whole of the first year's gross premium is available for current mortality and expenses, there can be no terminal reserve set up until the end of the second year.   It is also clear that this

---

* That is, the premium on a $1,000 ordinary life policy as of age 36.

reserve from year to year will be a little smaller than the full level net premium reserve until the policy matures.

Example 1. For an ordinary life policy of $1,000 taken at age 30, find the terminal reserve for the first three policy years under the preliminary term system of valuation. Also find reserve for the twentieth year.

Solution. The insurance for the first year is term insurance and there is no first year reserve. To get the terminal reserve for the second year we make use of (3) Art. 91, letting $x = 31$. Then

$$_1V_{31} = u_{31}P_{31} - k_{31}$$

$$= 1.043884\,(0.01768) - 0.008583$$

$$= 0.00987,$$

and $1,000\,_1V_{31} = 1,000\,(0.00987) = \$9.87$ (2nd year reserve).

Also, $$_2V_{31} = u_{32}(_1V_{31} + P_{31}) - k_{32}$$

$$= 1.043986\,(0.00987 + 0.01768) - 0.008682$$

$$= 0.020179,$$

and $1,000\,_2V_{31} = 1,000\,(0.020179) = \$20.18$ (3rd year reserve).

The reserve for the 20th year will be the 19th year reserve for age 31. From (4), Art. 92, we get

$$_{19}V_{31} = A_{50} - P_{31}\,a_{50}$$

$$= 0.50849 - 0.01768\,(14.5346)$$

$$= 0.25151,$$

and $1,000\,_{19}V_{31} = 1,000\,(0.25151)$

$$= \$251.51 \text{ (20th year reserve).}$$

According to the full level premium method, the reserve for the third year would have been $29.33 and that for the twentieth year would have been $258.64. The student will observe that the difference between the reserves, for any particular year, according to the two methods decreases as the age of the policy increases. In fact, the reserves for the fortieth year differ by only $3.64.

Example 2. For a 20-payment life policy of $1,000 taken at age 30, find the terminal reserve for the first three policy years under the preliminary term system. Also find the reserve for the twentieth year.

Solution. The insurance for the first year is term insurance and there is no first year reserve. To get the terminal reserve for the second year we make use of (3) Art. 91, letting $x = 31$. Then

$$_1V_{31} = u_{31} \cdot {}_{19}P_{31} - k_{31}$$

$$= 1.043884 \,(0.02601) - 0.008583$$

$$= 0.018568,$$

and $\quad 1,000 \,_1V_{31} = 1,000 \,(0.018568)$

$$= \$18.57 \text{ (2nd year reserve)}.$$

$$_2V_{31} = u_{32}({}_1V_{31} + {}_{19}P_{31}) - k_{32}$$

$$= 1.043986 \,(0.018568 + 0.02601) - 0.008682$$

$$= 0.037859,$$

and $\quad 1,000 \,_2V_{31} = 1,000 \,(0.037859)$

$$= \$37.86 \text{ (3rd year reserve)}.$$

The reserve for the 20th year will be the 19th year reserve on a 19-payment life taken at age 31. From (6), Art. 92, we get

$$_{19:19}V_{31} = A_{50} = 0.50849,$$

and $1,000 \,_{19:19}V_{31} = 1,000 \,(0.50849)$

$$= \$508.49 \text{ (20th year reserve)}.$$

According to the full level premium method, the reserve for the third year would have been $53.94 and that for the twentieth year would have been $508.49. We observe that the difference in reserve by the two methods is $16.08 at the end of the third year. However, at the end of 20 years there is no difference.

101. Modified preliminary term valuation.—In Art. 100 we mentioned the fact that the preliminary term method of valuation is objectionable when applied to limited payment life and endowment policies with short premium paying periods. This can best be illustrated by an example. Suppose we apply this method of valuation to a fifteen-payment endowment policy for $1,000 taken at age 35. The office premium is $67.92 and since the natural premium for the first year is $8.65 there would be a first year loading of $59.27. This is entirely too much for first year expenses. It is evident then that the preliminary term system should be modified when applied to short premium paying periods.

We found that in the case of the ordinary life policy taken at age 35 there was, according to the preliminary term system, a first year loading of $17.90 and this was adequate for initial expenses. Hence, if this amount is sufficient in the one case, it seems reasonable that the same amount, or but little more, should be adequate for limited payment and endowment policies of short premium paying periods. This then suggests a modification. *The ordinary life premium at any age forms the basis of the amount which can be used for first year expenses for limited payment and endowment policies taken at the same age.*

Another method of modification is that provided by the laws of Illinois, usually known as the " Illinois Standard." *Under the Illinois plan, twenty payment life policies and all other policies having premiums smaller than that of the twenty payment life policy for that age are valued on the preliminary term plan without any modification.* * *Then the twenty payment life premium forms the basis of the amount which can be used for first year expenses on all policies whose premiums are greater than that of the twenty payment life.*

The principles underlying the two methods of modification were recognized by the " Committee of Fifteen," composed of Insurance Commissioners and Governors, in 1906, and since that time the laws of many states have been amended so as to adopt the recommendations of this committee.

Some other states have other ways of modifying the preliminary term system, but the two modifications that we have here described will be sufficient for this discussion. We will now illustrate each of the above methods with an example.

Example 1.   Find the terminal reserves for the first three years on a fifteen-year endowment policy of $1,000, issued at age 25, valued according

---

* This is spoken of as the *full preliminary term plan* to distinguish it from any one of the modified plans.

to the modified preliminary term system with the ordinary life as a basis of modification.

Solution. We shall base all our computations on an insurance of $1 and then multiply by 1,000. The net premium for the first year is the natural premium plus a certain excess, e. The subsequent net annual premiums are the net ordinary life premiums for age 26, plus the same excess, e, required to mature the policy.

Neglecting e each year the value of the policy at the end of 15 years would be the full level net premium terminal reserve of the 14th policy year on an ordinary life policy of $1 issued at age 26, or $_{14}V_{26}$. However, at the end of 15 years the policy must have a value of $1. Hence, the excess payment of e each year must provide at maturity a pure endowment of

$$(1 - {_{14}}V_{26}).$$

This excess, e, is the annual payment on a forborne temporary annuity due at age 25 (Art. 79), that will accumulate in 15 years to

$$(1 - {_{14}}V_{26}).$$

Hence,
$$e\left(\frac{N_{25} - N_{40}}{D_{40}}\right) = (1 - {_{14}}V_{26}),$$

and
$$e = (1 - {_{14}}V_{26})\frac{D_{40}}{N_{25} - N_{40}}.$$

From (4), Art. 92, we get

$$_{14}V_{26} = A_{40} - P_{26}\, a_{40}$$

$$= 0.41003 - 0.01548\,(17.4461)$$

$$= 0.13997,$$

since,
$$P_{26} = 0.01548.$$

Then,
$$e = (1 - 0.13997)\,\frac{19{,}727.4}{770{,}113 - 344{,}167}$$

$$= 0.03983.$$

The terminal reserve for the first year is

$$_{1}V_{25} = u_{25}(e + A^1_{25\,\overline{1}|}) - k_{25} \quad [(2)\text{ Art. } 91]$$

$$= u_{25}\cdot e = 1.043415(0.03983)$$

$$= 0.04156,$$

since, $\qquad u_{25} \cdot A^1_{25\,\overline{1}} = k_{25}.$ [(9) Art. 84 and Exercise 1, Art. 91]

Then, $\qquad 1{,}000\ _1V_{25} = 1{,}000(0.04156) = \$41.56$ (1st year reserve).

$$_2V_{25} = u_{26}(_1V_{25} + P_{26} + e) - k_{26}$$

$$= 1.043415(0.04156 + 0.01548 + 0.03983)$$

$$- 0.008197 = 0.09288.$$

Then, $\qquad 1{,}000\ _2V_{25} = 1{,}000(0.09288) = \$92.88$ (2nd year reserve).

$$_3V_{25} = u_{27}(_2V_{25} + P_{26} + e) - k_{27}$$

$$= 1.043554(0.09288 + 0.01548 + 0.03983)$$

$$- 0.008264 = 0.14638.$$

Then, $\qquad 1{,}000\,_3V_{25} = 1{,}000(0.14638) = \$146.38$ (3rd year reserve).

According to the full level premium method, the reserve for the first three years would be \$48.87, \$99.81, and \$152.90, respectively. We notice that the difference between the two methods for the first year is \$7.31 and for the third year the difference is \$6.52. There would be no difference for the fifteenth year.

Example 2. Find the terminal reserves for the first three years on a ten-year endowment policy of \$1,000, issued at age 25, valued according to the Illinois standard.

Solution. The net premium for the first year is the natural premium, $A^1_{25\,\overline{1}}$, plus an excess e. The subsequent net annual premiums are the net premiums on a nineteen-payment life taken at age 26, plus the same excess e.

Neglecting e each year the value of the policy at the end of 10 years would be the full level net premium terminal reserve of the 9th policy year on a nineteen-payment life policy of \$1, issued at age 26, or $_{9:19}V_{26}$. However, at the end of 10 years the policy must have a value of \$1.

Hence, the excess payment of e each year must provide at maturity a pure endowment of $(1 - {}_{9:19}V_{26})$.

Therefore, $e\left(\dfrac{N_{25} - N_{35}}{D_{35}}\right) = (1 - {}_{9:19}V_{26})$

and $\qquad e = (1 - {}_{9:19}V_{26})\dfrac{D_{35}}{N_{25} - N_{35}}.$

From (6), Art. 92

$$_{9:19}V_{26} = A_{35} - {}_{19}P_{26} \cdot a_{35\,\overline{10|}}$$

$$= 0.17458,$$

since, $$A_{35} = 0.37055,$$

and $$_{19}P_{26} = 0.02368, \quad [(6) \text{ Art. } 83]$$

$$a_{35\,\overline{10|}} = 8.27575. \quad [(10) \text{ Art. } 76]$$

Then, $$e = (1 - 0.17458)\,\frac{24{,}544.7}{770{,}113 - 456{,}871}$$

$$= 0.06468.$$

Hence, $$_1V_{25} = u_{25} \cdot e = 1.043415(0.06468)$$

$$= 0.06749,$$

and $$1{,}000\,_1V_{25} = 1{,}000(0.06749) = \$67.49 \text{ (1st year reserve)}.$$

$$_2V_{25} = u_{26}(_1V_{25} + {}_{19}P_{26} + e) - k_{26}$$

$$= 1.043484(0.06749 + 0.02368 + 0.06468)$$

$$- 0.008197 = 0.15443,$$

and $$1{,}000\,_2V_{25} = 1{,}000(0.15443) = \$154.43 \text{ (2nd year reserve)}.$$

$$_3V_{25} = u_{27}(_2V_{25} + {}_{19}P_{26} + e) - k_{27}$$

$$= 1.043554(0.15443 + 0.02368 + 0.06468)$$

$$- 0.008264 = 0.24510,$$

and $$1{,}000\,_3V_{25} = 1{,}000(0.24510) = \$245.10 \text{ (3rd year reserve)}.$$

According to the full level premium method, the reserve for the first year would be \$82.08, for the second \$167.66, and for the third \$256.92. The difference between the two methods for the first year is \$14.59 and the difference for the third year is \$11.82.

Note.—" It should be noted that a modification of premiums and reserves is employed solely for the purpose of providing for large preliminary expenses in the first policy year, and does not in any way affect the yearly amount of gross premium actually paid to the

company by the policyholder. The modification is purely an internal transaction of the life insurance company, which releases a larger part of the gross premium for expenses in the first year and defers to a later date the setting up of a part of the reserve." *

102. Concluding remarks.—Before completing this elementary treatment of life insurance, we wish to emphasize the fact that we have attempted to give a mere introduction into a broad field. There are many topics that we have not touched. For the student who is interested in a further study of this important field, we suggest the following books:

Moir, Henry, *Life Assurance Primer*, The Spectator Company, New York City.

Menge, W. O., and Glover, J. W., *An Introduction to the Mathematics of Life Insurance*, The Macmillan Company, New York City.

Knight, Charles K., *Advanced Life Insurance*, John Wiley and Sons, New York City.

Spurgeon, E. F., *Life Contingencies*, The Macmillan Company, New York City.

Exercises

1. For a twenty payment life policy of $1,000, taken at age 25, find the terminal reserve for the 15th policy year both under the level net premium system and under the preliminary term system of valuation.

2. Find the terminal reserve for the first three years on a 20-year endowment policy of $1,000, issued at age 40, valued according to the modified preliminary term system with the ordinary life as a basis of modification.

3. Solve Exercise 2, using the Illinois Standard.

4. If the gross premium of a limited payment life policy of $1 on (x) is found by increasing the net premium by a certain percentage r and adding to this a certain percentage s of the net ordinary life premium and further increasing this by a constant c, per $1,000 insurance, show that the gross premium may be expressed by the formula

$$_nP'_x = P_x \cdot s + {}_nP_x(1 + r) + \frac{c}{1,000}. \tag{3}$$

5. Making use of formula (3) find the office premium on a fifteen payment life policy of $1,000 for the ages 20, 25, 30 and 35, where $r = 16\frac{2}{3}\%$, $s = 16\frac{2}{3}\%$, and $c = 50$ cents.

6. Making use of (1) find the office premiums on an ordinary life policy of $1,000 for the ages 20, 25, 30 and 35, where $r = 33\frac{1}{3}\%$ and $c = 50$ cents.

---

* Menge, W. O. and Glover, J. W., *An Introduction to the Mathematics of Life Insurance*, 1935, p. 108.

7. The formula

$$P'_{x\,\overline{n}|} = P_{x} \cdot s + P_{x\,\overline{n}|}(1 + r) + \frac{c}{1,000} \tag{4}$$

gives the gross premium for an n-year endowment policy of \$1 on (x). Interpret the formula.

8. Making use of (4) find the office premium of a fifteen year endowment policy of \$1,000 for the ages 20, 25, 30 and 35, where $r = s = 16\frac{2}{3}\%$ and $c = 50$ cents.

Problems

1. By the terms of a will the income at 5% annually of a \$20,000 estate goes to a widow aged 50 during her lifetime. Find the value of her inheritance.

2. The will in Problem 1 requires that the residue of the estate shall go to a hospital when the widow dies. Find the value of this residue at the time the inheritance comes to the widow.

3. By the terms of a will the income at 5% annually of a \$20,000 estate goes to a son aged 25 for 10 years, or so long as he lives during the 10 years, after which the residue of the estate goes to a university. Find the present value of each legacy.

4. A widow aged 55 is to receive a life income of \$25,000 a year from her husband's estate. The inheritance tax law requires that the bequest be valued on a $3\frac{1}{2}\%$ basis. The law grants the widow an exemption of \$5,000, and on the remainder of the cash value of her inheritance a tax of 3% must be paid of the first \$50,000 over the exemption value, and 5% on the next \$50,000, then 10% on the cash value in excess of \$100,000. Find the inheritance tax on this bequest.

5. Under the Illinois Standard, the terminal reserve at the end of 25 years of a \$1,000, 15-payment life policy issued at age 35 is \$626.92. If the full amount of this reserve is allowed as cash surrender value, how much paid-up insurance will it purchase?

6. Under the full preliminary term valuation, the terminal reserve at the end of 25 years on a \$1,000 ordinary life policy issued at age 35 is \$400.25. If the full amount of this reserve is used to purchase extended insurance, how long is the extension?

7. Find the net first year and renewal premiums for an ordinary life policy of \$1,000 issued at age 25 according to the full preliminary term method.

8. Same as Problem 7 but for a 20-payment life policy.

9. Same as Problem 7 but for a 20-payment 20 year endowment policy.

REVIEW PROBLEMS

Percentage

1. A building worth $15,000 is insured for $12,000. For what per cent of its value is it insured?

2. A merchant fails, having liabilities of $30,000, and resources of $18,000. What per cent of his debts can he pay? He owes Joe Brown $6,500. How much will Brown receive?

3. A manufacturer sells to a wholesaler at a profit of 20%. The wholesaler sells to the retailer at a 25% profit. The retailer sells to the consumer at a profit of 60%. If the consumer pays $28.80, what is the cost to the manufacturer? To the wholesaler? To the retailer?

4. Which is better for the purchaser, a series of discounts of 30%, 20%, and 10%, or a single discount of 50%? What would be the difference on a bill of $1,000?

5. A coat listed at $100 is bought subject to discounts of 20%, 10%, and $8\frac{1}{3}\%$. (a) Find the net cost rate factor. (b) Find the net cost. (c) What single discount rate is equivalent to the given series of discounts? [*Alg.: Com.—Stat.*, p. 98.]

6. A coat cost a dealer $66. He marked the coat so that he could "drop" the marked price 20% and still sell it so as to make a profit of 10% on the cost. What was the selling price? The marked price?

7. I can buy a living room suite for $150, less $33\frac{1}{3}\%$ and 20%. From another dealer I can get the same suite for $125, less 25% and $12\frac{1}{2}\%$. The terms in each case are "net 30 days or 2% off for cash." What is the least amount of cash for which I can purchase the suite?

8. A bill of goods is purchased subject to discounts of r_1 and r_2. Show that an equivalent single discount is their sum less their product.

9. Goods are bought subject to discounts of 25% and 20%. Find the marked price per dollar list if the goods are to be marked to realize a profit of $33\frac{1}{3}\%$.

10. At what price should goods costing $432 be marked to make a profit of 25% of the cost after allowing a discount of 20%?

Simple Interest and Discount

11. A note for $1,200 bearing interest at 5% and due in 8 months is sold to an investor to whom money is worth 6%. What does the investor pay for the note?

12. I purchased $400 worth of lumber from a dealer who will allow me credit for 60 days. If I desire to pay immediately, what should he be willing to accept if he estimates that he earns 6% on his money?

13. A real estate dealer received two offers for a piece of property. Jones offered $3,000 cash and $5,000 in 6 months; Smith offered $5,000 cash and $3,000 in 1 year. Which was the better offer on a 6% basis?

14. The cash price of a washing machine is $75. It is bought for $10 down and $10 a month for 7 months. What rate of interest is paid?

15. I borrow $500 for six months from a bank that charges 6% in advance. For what amount do I make the note?

16. I owe $500 due in 3 months and $600 due in 12 months. I desire to pay these debts by making equal payments at the ends of six and nine months. On a 6% basis, find the equal payments. Choose 12 months as a focal date.

17. I owe William Brown $500 due in 3 months with interest at 8% and $800 due in 12 months without interest. We agree that I may liquidate these debts with equal payments at the ends of six and nine months on a 6% basis. Find the equal payments by focalizing at 12 months.

18. When could I liquidate the debts in Problem 16 by a single payment of $1,100, the equities remaining the same?

19. When could I liquidate the debts in Problem 17 by a single payment of $1,310, the equities remaining the same? Solve by setting up an equation of value with focal date at 12 months.

20. $1,000   LOUISVILLE, KENTUCKY
                                             February 12, 1945

     Nine months after date I promise to pay Robert Brown, or order, one thousand dollars with interest at 7% from date.

                                    Signed, GEORGE SANDERS.

(a) Five months after date, Brown sold the note to Bank B which operates on a 6% discount basis. What did Brown receive for the note?

(b) Bank B held the note for 1 month and then sold it to a Federal Reserve Bank which operates on a 4% discount basis. What did Bank B gain on the transaction?

Compound Interest and Discount

21. A man buys a house for $6,000, pays $2,000 cash, and gives a mortgage note at 6% for the balance. If he pays $1,000 at the end of two years and $1,000 at the end of 4 years, what will be the balance due at the end of 5 years?

22. I owe $1,500. I arrange to pay R at the end of 1 year, $2R$ at the end of 2 years and $3R$ at the end of 3 years. If money is worth 5% find R.

23. If $(j = .08, m = 12)$, find i.

24. If a finance company charges 1% a month on loans, what is their effective earning?

25. I owe two sums: $700 due in 6 months without interest and $1,500 due in 18 months with interest at $(j = .06, m = 2)$. On a $(j = .05, m = 2)$ basis what amount will liquidate these debts at the end of 1 year?

26. A lot is priced at $2,000 cash. A buyer purchased it with equal payments now and at the end of one year. On a 6% basis, what was the amount of the payments?

27. What sum payable in 2 years will discharge two debts, $1,500 due in 3 years with interest at 5%, and $2,000 due in four years with interest at 6%, money being worth 4%?

28. A merchant sells goods on the terms "net 90 days or 2% off for cash." Find the highest nominal rate of interest, j_4, at which a customer should borrow money in order to pay cash. Find the effective rate.

29. If $i = .06$, find d, j_4, and f_4.

30. If $d = .06$, find i, f_4, and j_4.

31. If $f_4 = .06$, find i, d, and j_4.

32. If $j_4 = .06$, find i, d, and f_4.

33. The Jones Lumber Co. estimates that money put into their business yields $1\frac{1}{2}\%$ a month. Find the highest discount rate, $\dfrac{f_{12}}{12}$, they can afford to offer to encourage payment of a bill due in one month.

34. State a problem for which the answer would be the value of x determined by the equation:

$$7,860 = x(1.03)^{-2} + x(1.03)^{-4} + x.$$

35. State a problem for which the answer would be the value of x determined by the equation:

$$x(1.04)^2 + x(1.04) + x = 3,000(1.025)^6 + 2,000(1.04)^{-1}.$$

36. I can buy a piece of property for $9,800 cash or for $6,000 cash and payments of $2,000 at the ends of 1 year and 2 years. Should I pay cash if I can invest money at 6%?

Annuities

37. A purchaser of a farm agreed to pay $1,000 at the end of each year for 10 years. (*a*) What is the equivalent cash price if money is worth 5%? (*b*) At the end of 5 years, what must the purchaser pay if he desires to completely discharge his remaining liability on that date?

38. I owe $6,000 due immediately. If money is worth $(j = .04, m = 4)$, what equal quarterly payments will discharge the debt if the first payment occurs at the end of 3 years and the last at the end of 10 years?

39. A man buys a home for which the cash price is $10,000. He pays $1,200 down and agrees to pay the balance with interest at $(j = .05, m = 2)$ by payments of $1,200 at the end of each half-year as long as necessary with a final partial payment at the end of the last payment period. How many full payments are necessary? What is the final partial payment?

40. In Problem 39, find the principal outstanding just after the fifth payment of $1,200.

41. Prove that $(1 + i)s_{\overline{n}|i} + 1 = s_{\overline{n+1}|i}$
   (*a*) by verbal interpretation;
   (*b*) algebraically.

42. A man buys a house of cash value $25,000. He pays $5,000 down and agrees to pay the balance with payments of $1,000 at the beginning of each half-year for 14 years. Find the nominal rate j_2 and the effective rate i that the purchaser pays.

43. An annuity of $100 a year amounts to $3,492.58 in 20 years. Find i.

44. A man purchased a property paying $3,000 down and $500 at the end of each half-year for 10 years. If money was worth ($j = .07, m = 2$), what was the equivalent cash price?

45. A debt of $10,000 is being amortized, principal and interest, by payments of $1,000 at the end of each half-year. If interest is at ($j = .04, m = 2$), what is the final payment?

46. The sum of $500 was paid annually into a fund for five years, and then $800 a year was paid. If the funds accumulated at 4%, when did the total amount to $12,000? Obtain the final payment.

47. The sum of $100 was deposited at the end of each month for 8 years in a bank that paid 4% effective. What was the value of the account two years after the last deposit if no withdrawals were made?

48. A man deposited $200 at the end of every quarter in a savings bank that paid $3\frac{1}{2}\%$ effective. When did the account total $10,000? What was the final partial payment?

49. A machine costs $2,000 new and must be replaced at the end of 15 years at a cost of $1,900. Find the capitalized cost if money can be invested at 4%.

50. Is it more profitable for a city to pay $2 per square yard for paving that lasts five years than to pay $3 per square yard for paving that lasts 8 years, money being worth 5%?

51. A lawn mower costs $10 and will last 3 years. How much can one afford to pay for a better grade of mower that will last 5 years, money worth 4%?

Sinking Funds and Amortization

52. Find the annual payment necessary to amortize in 5 years a debt of $1,000 which bears interest at 7%. Construct a schedule.

53. A corporation issues $1,000,000, 6% bonds, dividends payable semi-annually. The dividends are paid as they fall due and the corporation makes semi-annual deposits into a sinking fund that will accumulate at $j_2 = .04$ to their face value in 15 years. Find the sinking fund deposit. Find the total semi-annual expense to the corporation.

54. A debt of $100,000 bearing interest at 5% effective will be retired by a sinking fund at the end of 10 years that earns 4% effective. Find the total annual expense. At what rate of interest could the debtor just as well have agreed to amortize the debt?

55. Which will be better, to repay a debt of $25,000, principal and interest at 5%, in 10 equal annual payments, or to pay 6% interest on the debt each year and accumulate a sinking fund of $25,000 in 10 years at 4%?

56. A man purchases a house for $12,000 paying one-half down. He arranges to pay $1,500 per year principal and interest on the remaining amount until the debt is paid. How many payments of $1,500 are made and what is the final payment at the end of the year of settlement if the debt bears interest at 6%?

57. At the end of two years what was the purchaser's equity in the house in Problem 56?

Depreciation

58. A dynamo costing $5,000 has an estimated life of 10 years and a scrap value of $200. Find the constant rate of depreciation. What is the book value of the machine at the end of 5 years?

59. What is the annual payment into the depreciation fund of the machine in Problem 58 if the fund increases at 4%? What is the book value of the machine at the end of 5 years?

60. A plant consists of three parts described by the table. Find the total annual depreciation charge on a 3% basis:

Part	Est. Life	Cost	Scrap Value
A.................	40	$20,000	$1,000
B.................	20	8,000	200
C.................	15	10,000	2,000

61. A Diesel engine costs $50,000, lasts 20 years and has a salvage value of $5,000. (a) Find the amount that should be in the sinking fund at the end of 10 years at $4\frac{1}{2}\%$. (b) What is the amount of depreciation during the eleventh year?

62. An old machine turns out annually 1,200 units at a cost of $3,000 for operation and maintenance. It is estimated that at the end of 12 years it will have a salvage value of $500. To replace the old machine by a new one would cost $15,000, but 1,500 units could be turned out annually at an average annual cost of $3,500 and this could be maintained for 25 years with a salvage value of $1,000. On a 6% basis what is the value of the old machine?

63. What number of units output annually of the new equipment in Problem 62 would reduce the value of the old machine to $4,000, all other data remaining the same?

64. What number of units output of the new machine in Problem 62 would render the old machine worthless?

Valuation of Bonds

65. Find the cost of a $1,000, 5% J. and J. bond, redeemable at par in 10 years, if bought to yield $(j = .06, m = 2)$.

66. Find the cost of a $1,000 bond, redeemable in 8 years at 106, paying 6% convertible quarterly if bought to yield 8% effective.

67. Find the cost of the bond described in Problem 66 if bought to yield $(j = .08, m = 4)$.

68. A $10,000, 4% J. and J. bond, redeemable at par January 1, 1940, was bought July 1, 1936, to yield $(j = .06, m = 2)$. Construct a schedule for the accumulation of the discount.

69. What was a fair price for the bond described in Problem 68 if bought on August 13, 1936?

70. A $10,000, 7% J. and J. bond, was sold on June 1 at $102\frac{1}{4}$ and accrued interest. What was the selling price?

71. A $1,000, 5% J. and J. bond, redeemable at par in 10 years was purchased for $970. Find the yield rate, j_2.

Miscellaneous

72. If \$100 invested at 5% simple interest accumulates to the same amount as \$100 invested at 4% simple discount, find the time the investment runs.

73. Show that it takes three times as long for a principal P to quadruple itself at $i\%$ as it does to double itself.

74. Jones considers two offers for a piece of property. A offers \$3,000 cash and \$5,000 in 6 months. B offers \$5,000 cash and \$3,000 in 1 year. On a 5% simple interest basis, which is the better offer? Find the difference in the present values of the two offers.

75. If D_o and D_e denote ordinary and exact simple discounts on an amount S for n years at $d\%$, show that $D_e = D_o - D_o/73$. [Compare (6), page 4.]

76. How long will it take a principal P to double itself at the compound discount rate, $d\%$?

77. Prove: $\dfrac{1}{a_{\overline{n}|i}} = \dfrac{1}{s_{\overline{n}|i}} + d$.

78. Prove: $a_{\overline{n}|i} = \dfrac{1 - v^n}{d}$.

79. If R_r denotes the amount in the depreciation fund at the end of r years under the S.F. plan, prove that $R_r = Rs_{\overline{r}|i}$.

80. If D_r denotes the depreciation charge during the rth year under the S.F. plan, prove that $D_r = R(1 + i)^{r-1}$. [See Exercise 79 above.]

81. If $a_{\overline{n}|i} = x$ and $s_{\overline{n}|i} = y$, prove that $i = (y - x)/xy$.

82. A debt D bearing interest at $i\%$ is being amortized by equal annual payments R. Show that the indebtedness remaining unpaid at the end of r years is $D - (R - Di)s_{\overline{r}|i}$.

83. Let $C = S$, and show that (2), page 142, can be reduced to form (12′), page 135. Explain how this can be true.

84. An alumnus, 50 years of age, proposes to give his college \$50,000 provided the college will pay him \$2,500 a year as long as he lives. If the college can borrow money at 4%, should it accept the proposition?

85. A note for \$3,000 with interest (compound) at 5%, due in 5 years, is discounted at the end of 2 years at discount rate of 4% compounded semi-annually. Find the proceeds and the discount.

86. A teacher provided for retirement by depositing \$300 a year with a trust company that granted him $(j = .04, m = 2)$ interest rate. At the end of 25 years he retired and withdrew \$1,000 a year. For how many years could he enjoy this annuity?

87. It is estimated that a copper mine will produce \$30,000 a year for 18 years. If the investor desires to earn 12% on the investment and can earn 4% on the sinking fund, what can he afford to pay for the mine?

88. A timber tract is priced at \$1,000,000. It is estimated the tract will yield a net annual income of \$200,000 for 10 years and that the cleared land will be worth \$20,000. The lumber company wishes to earn 10% on the investment and can earn 4% on redemption funds. Is the tract a good buy?

89. Find the constant per cent by which the value of a machine is decreased if its cost is \$12,000, its scrap value \$2,000, and its estimated life 15 years.

90. Expand $(1 + j/m)^m$ by the binomial theorem, let m become infinite, and show that

$$\lim_{m \to \infty} \left(1 + \frac{j}{m}\right)^m = 1 + j + \frac{j^2}{2!} + \frac{j^3}{3!} + \cdots.$$

The series on the right is the infinite series expansion of e^j, where $e = 2.71828+$ and is called the base of the natural or Napierian logarithms. The series converges for all values of j. Thus, as m becomes infinite, $(1 + i)$ approaches e^j. (See page 139.)

When m becomes infinite, it is customary to replace j by δ. Thus, for continuous conversion we have

$$1 + i = e^\delta$$

$$\delta = \log_e (1 + i) = \frac{\log_{10} (1 + i)}{\log_{10} e} = \frac{\log_{10} (1 + i)}{.43429}.$$

The quantity δ is called the *force of interest*.

91. If $\delta = .06$, find i.

92. If $i = .06$, find δ.

93. Show that if the interest is converted continuously for n years, the accumulated value of S is

$$S = Pe^{n\delta}.$$

94. The population of Jacksonville increased continuously from 130,000 in 1930 to 173,000 in 1940. Find the continuous rate of increase. (Use results of Exercise 93 above.)

95. Proceed as in Exercise 90 and show that

$$\lim_{m \to \infty} \left(1 - \frac{f}{m}\right)^m = e^{-f}.$$

It is customary for continuous conversion of discount to replace f by δ'. Then we have

$$1 - d = e^{-\delta'}.$$

The quantity δ' is called *force of discount*.

96. Show that if the discount is converted continuously for n years, the discounted value of S is

$$P = Se^{-n\delta'}.$$

97. Find the amount of $1,000 for 10 years at 4% nominal, converted continuously.

98. A machine depreciated continuously from a value of $50,000 to a salvage value of $10,000 in 20 years. Find the continuous rate of depreciation.

99. Jones bought a truck for $2,000. Its estimated life was 5 years and its salvage value was $500. Jones estimated the truck earned $500 a year net. What did he earn on his investment if deposits for replacement earned 3%? (See page 135.)

100. A college invests $400,000 in a dormitory. It is estimated that the college will derive $25,000 net a year for 50 years at the end of which time the building will have a salvage value of $100,000. What will the college earn on its investment if deposits for replacement earn 3%? (See page 135.)

TABLE I.—COMMON LOGARITHMS OF NUMBERS
